Environmental Justice In Washington State: Is it Real, Or Does Washington EJ Just Look Good On Paper?

A Statement from Friends of Toppenish Creek, December 15, 2023

Environmental justice (EJ)
is the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation and enforcement of environmental laws, regulations and policies.

Fair treatment
means no group of people should bear a disproportionate share of the negative environmental consequences resulting from industrial, governmental and commercial operations or policies.

Meaningful involvement
means:

- People have an opportunity to participate in decisions about activities that may affect their environment and/or health;
- The public's contribution can influence the regulatory agency's decision;
- Community concerns will be considered in the decision making process; and
- Decision makers will seek out and facilitate the involvement of those potentially affected. [1]

* * * * * * * * *

Certain elements of Environmental Justice have been incorporated into WA State law by the Climate Commitment Act and the Healthy Environment for All (HEAL) Act. Environmental Justice has been codified in Washington under RCW 70A.02.

The Washington State Dept. of Ecology [2] and the Washington State Dept. of Commerce [3] have developed agency policies that proclaim adherence to the principles of Environmental Justice.

And yet . . . . In Sunnyside WA one of the largest manure methane bio-digesters in the U.S. [4] has been planned for over two years and the people of Sunnyside are largely unaware. South Yakima
County is classified as an underserved community with a population that is over 80% Latino [5]
and a median household income of $49,134. [6]

The Friends of Toppenish Creek have asked the Yakima County Commissioners, the Yakima Regional Clean Air Agency, and the WA State Dept. of Ecology to hold informational meetings regarding the proposed digester. The agencies have so far ignored the request.

On November 30, 2023, at considerable expense, FOTC partnered with Empowering Latinas in Leadership and Action (ELLA) and convened a meeting to inform the public. Prior to the meeting ELLA canvased Sunnyside neighborhoods near the site and contacted nearly 250 households. Only five of the households had even heard of the digester.

Meanwhile permits are in process and contracts are being signed. The Port of Sunnyside sold property for the digester to project sponsors, Pacific Ag, in 2022. The City of Sunnyside has agreed to make million dollar improvements to nearby roads to accommodate the 140 truck trips per day that would bring manure from outlying farms to the city and the digester. The WA State Department of Commerce has allocated $500,000 for the project.

Already, in June of 2023, the City of Sunnyside has issued a mitigated determination of non-significance (MDNS) for the proposal under the WA State Environmental Policy Act (SEPA). The City of Sunnyside is the Lead Agency for SEPA evaluation of the project. Environmental and EJ advocates believe that the City of Sunnyside should have completed an Environmental Impact Statement (EIS) before issuing the MDNS. An Environmental Impact Statement means looking at all aspects of the project in depth rather than basing a decision on short answers to an Environmental Checklist completed by the proponents.

FOTC asks, “How can anyone construct a bio-digester that produces 850,000 MMBTU’s of natural gas per year that does not have an impact on the environment?” [7] and “How can the WA State Department of Commerce and the WA State Department of Ecology endorse and support a project that tramples the principles of Environmental Justice, by excluding this underserved community from decision making?”

Here are a few of the questions that require answers before breaking ground:

· What are the emergency plans in case of a tank explosion at this project?

· What is the expected life of a digester tank? Of pipes that transport methane, manure, and digestate?

· Will SS RNG truck drivers possess Commercial Drivers Licenses (CDLs) or will the SS RNG use the agricultural exemption for drivers who transport agriculture goods?

· Which air emissions will be monitored and where? Ammonia? Hydrogen sulfide? Methane? Carbon dioxide? Particulate matter? Other?

· How much will dairies be paid per ton of manure?

· How long will the digesters operate in the mesophilic range? How long will the digesters operate in the thermophilic range? This makes a difference in how many pathogens are destroyed by digestion. [8]

· Are there any requirements in place to ensure that digestate, the material left over after harvesting methane, will be applied to fields at agronomic rates?

· Will the proposed RNG facility digest the carcasses of unwanted farm animals?

· Who opposes completion of an EIS and why?

Sincerely,

Friends of Toppenish Creek

Dear Mr. Martin,

Please see the attached comments from Friends of Toppenish Creek regarding the Sunnyside RNG project. I will send supporting documents in a second email.

Thank you.

[3] WA State Dept. of Commerce. Environmental Justice. https://www.commerce.wa.gov/program-index/environmentaljustice/

And yet . . . . In Sunnyside WA one of the largest manure methane bio-digesters in the U.S.[4] has been planned for over two years and the people of Sunnyside are largely unaware. South Yakima

County is classified as an underserved community with a population that is over 80% Latino[5] and a median household income of $49,134.[6]

The Friends of Toppenish Creek have asked the Yakima County Commissioners, the Yakima Regional Clean Air Agency, and the WA State Dept. of Ecology to hold informational meetings regarding the proposed digester. The agencies have so far ignored the request.

On November 30, 2023, at considerable expense, FOTC partnered with Empowering Latinas in Leadership and Action (ELLA) and convened a meeting to inform the public. Prior to the meeting ELLA canvased Sunnyside neighborhoods near the site and contacted nearly 250 households. Only five of the households had even heard of the digester.

Meanwhile permits are in process and contracts are being signed. The Port of Sunnyside sold property for the digester to project sponsors, Pacific Ag, in 2022. The City of Sunnyside has agreed to make million dollar improvements to nearby roads to accommodate the 140 truck trips per day that would bring manure from outlying farms to the city and the digester. The WA State Department of Commerce has allocated $500,000 for the project.

Already, in June of 2023, the City of Sunnyside has issued a mitigated determination of non-significance (MDNS) for the proposal under the WA State Environmental Policy Act (SEPA). The City of Sunnyside is the Lead Agency for SEPA evaluation of the project.

Environmental and EJ advocates believe that the City of Sunnyside should have completed an Environmental Impact Statement (EIS) before issuing the MDNS. An Environmental Impact Statement means looking at all aspects of the project in depth rather than basing a decision on short answers to an Environmental Checklist completed by the proponents.

FOTC asks, "How can anyone construct a bio-digester that produces 850,000 MMBTU's of natural gas per year that does not have an impact on the environment?"[7] and "How can the WA State Department of Commerce and the WA State Department of Ecology endorse and support a project that tramples the principles of Environmental Justice, by excluding this underserved community from decision making?"

Here are a few of the questions that require answers before breaking ground:

---

[4] Renewable Natural Gas Project Introduction to the Port of Sunnyside September 6, 2022

[5] About 70% of the Latino families in South Yakima County speak Spanish at home. About 25% of the population does not speak English well according to the U.S. Census for 2022

[6] The median household income in Yakima County is $64,910. The median household income in Washington State is $90,325, according to the U.S. Census for 2022.

[7] Risks include increased emissions of hazardous air pollutants and greenhouse gasses, increased traffic, potential leaching to the underlying aquifer that is already contaminated, fires, and explosions.

- What are the emergency plans in case of a tank explosion at this project?
- What is the expected life of a digester tank? Of pipes that transport methane, manure, and digestate?
- Will SS RNG truck drivers possess Commercial Drivers Licenses (CDLs) or will the SS RNG use the agricultural exemption for drivers who transport agriculture goods?
- Which air emissions will be monitored and where? Ammonia? Hydrogen sulfide? Methane? Carbon dioxide? Particulate matter? Other?
- How much will dairies be paid per ton of manure?
- How long will the digesters operate in the mesophilic range? How long will the digesters operate in the thermophilic range? This makes a difference in how many pathogens are destroyed by digestion.[8]
- Are there any requirements in place to ensure that digestate, the material left over after harvesting methane, will be applied to fields at agronomic rates?
- Will the proposed RNG facility digest the carcasses of unwanted farm animals?
- Who opposes completion of an EIS and why?

Sincerely,

Friends of Toppenish Creek

3142 Signal Peak Road
White Swan, WA 98952

[8] Mesophilic means digestion at 86 to 115 degrees Fahrenheit. Thermophilic means digestion at 115 to 140 degrees Fahrenheit. Water boils at 212 degrees Fahrenheit.

Comments re Addendum to Sunnyside Renewable Natural Gas (SS RNG) SEPA document

Friends of Toppenish Creek is a 501 C (3) non profit group incorporated under the laws of Washington State and located in Yakima County. FOTC submits the following comments regarding an addendum submittal to a June 2023 SEPA review and mitigated determination of non-significance (MDNS) for a proposed Renewable Natural Gas (RNG) bio-digester at the Port of Sunnyside. The City of Sunnyside Notice of SEPA Addendum asked commenters to reference SEPA 2022.0200. We are not sure whether this is correct, or whether SEPA 2022.0200 exists.[1] The correct file number may be SEPA 2023.0200.

It is difficult to comment intelligently on this addendum submittal because the notice omits so much content. For example, the addendum includes a February 2023 New Source Review (NSR) application from Sunnyside RNG to the Yakima Regional Clean Air Agency (YRCAA) but omits the response from the YRCAA that rejected the application and requested more information.

FOTC believes that an MDNS should not have been issued until the City of Sunnyside and the public had the opportunity to review information on air emissions and traffic impacts. The MDNS was issued on June 22, 2023, but a Traffic Impact Analysis (TIA), that is part of the November 23, 2023 addendum letter, is dated July 10, 2023.

The Yakima Regional Clean Air Agency, as the agency with expertise on air, failed to comment on the May 2023 SEPA Review, as required by RCW 43.21C and WAC 197-11, and especially WAC 197-11-030, WAC 197-11-060(4), and WAC 197-11-502(2).

The City of Sunnyside did not have sufficient information to conclude no environmental impacts, and the public did not have sufficient information to comment intelligently on the May 2023 Environmental Review. The resulting MDNS is invalid due to withheld and/or insufficient information. See WAC 197-11-335, WAC 197-11-340(3), WAC 197-11-080.

* * * * * *

[1] FOTC does not find SEPA 2022.0200 in Ecology's State Environmental Policy Act (SEPA) Register at https://apps.ecology.wa.gov/separ/Main/SEPA/Search.aspx?SearchText=City%20of%20Sunnyside&SearchFields=All&County=YAKIMA&PageSize=10&SortColumn=LeadAgencyAscending&Page=17

According to a presentation by Pacific AG to the Port of Sunnyside[2] on September 6, 2022, the Sunnyside RNG facility could be "one of the largest ag waste anaerobic digesters in the nation."[3]

Realistically, how can "one of the largest waste anaerobic digesters in the nation" not have an impact on the environment?

The SS RNG project would:

- Produce between 800,000 & 950,000 MMBTUs of Renewable Natural Gas a year
- Produce and store methane, a flammable and explosive gas, in tanks with membrane covers
- Transfer the natural gas to a major pipeline
- Move 140 truckloads of manure every day from dairies to the digester
- Store digestate in stacks at the digester site and on farms
- Store liquid effluent from the digester in lagoons
- Spread digestate onto crop fields. There is insufficient information to determine the composition of the digestate and potential impacts on soil health and greenhouse gas emissions.

* * * * * * *

Manure bio-digesters are known to experience spills and explosions.[4] These adverse impacts are not expected to occur, but when they do occur the impacts are grave. Washington law accounts for this in WAC 197-11-794 (2).

FOTC has requested more information regarding fires and spills from Pacific AG, Sunnyside RNG, and Yakima County Emergency Services. The City of Sunnyside should not take further action on the SS RNG MDNS until this information arrives, and answers satisfy potentially impacted people.

* * * * * * *

FOTC believes the City of Sunnyside violated many sections of Washington SEPA law when the city issued the June 22, 2023 MDNS. These alleged violations are listed below. FOTC believes that the MDNS should be rescinded pursuant to WAC 197-11-340(3), a determination of non-significance (DNS) should be issued, and an Environmental Impact Statement (EIS) completed. Conducting a thorough EIS is the only way to adequately determine the environmental consequences of constructing such a large digester.

[2] See Attachment 1

[3] Harrison Pettit from Pacific Ag said this was not true at a public meeting in Sunnyside on November 30, 2023.

[4] See Attachment 2

WAC 197-11-030

Policy.

(1) The policies and goals set forth in SEPA are supplementary to existing agency authority.

(2) Agencies shall to the fullest extent possible:

(a) Interpret and administer the policies, regulations, and laws of the state of Washington in accordance with the policies set forth in SEPA and these rules.

(b) Find ways to make the SEPA process more useful to decision makers and the public; promote certainty regarding the requirements of the act; reduce paperwork and the accumulation of extraneous background data; and emphasize important environmental impacts and alternatives.

(c) Prepare environmental documents that are concise, clear, and to the point, and are supported by evidence that the necessary environmental analyses have been made.

(d) Initiate the SEPA process early in conjunction with other agency operations to avoid delay and duplication.

(e) Integrate the requirements of SEPA with existing agency planning and licensing procedures and practices, so that such procedures run concurrently rather than consecutively.

(f) Encourage public involvement in decisions that significantly affect environmental quality.

(g) Identify, evaluate, and require or implement, where required by the act and these rules, reasonable alternatives that would mitigate adverse effects of proposed actions on the environment.

The City of Sunnyside did not, to the fullest extent possible, *Interpret and administer the policies, regulations, and laws of the state of Washington in accordance with the policies set forth in SEPA and these rules.* Sunnyside did not compel the Yakima Regional Clean Air Agency to provide comments on air impacts from:

- Potential leaks at the digester site
- Transport of manure and digestate
- Leaks in pipes that transport natural gas
- 140 round trip truck trips per day
- Storage of manure and digestate in stacks and lagoons
- Spreading and spraying digestate on crop fields

The City of Sunnyside did not *promote certainty regarding the requirements of the act*. Sunnyside sent conflicting messages to the public by telling the public that an appeal was authorized, improperly stating the appeal would be a closed appeal, scheduling an appeal, and then canceling the appeal. Sunnyside did not respond to reasonable questions regarding the proposed RNG project.[5]

[5] See Attachment 3 FOTC Request for the City of Sunnyside to reconsider an MDNS for the Sunnyside RNG project. The City did not answer our questions.

The City of Sunnyside did not *emphasize important environmental impacts and alternatives.* Sunnyside did not explore or list alternatives to the project or citing of the project. Sunnyside did not describe potential air impacts or potential impacts to ground and/or surface waters at the Port of Sunnyside where monitoring wells have high levels of nitrate[6] and the Sulphur Creek Wasteway traverses the area. The City of Sunnyside did not address the potential for fires and explosions.

There were no analyses to prove statements by the project proponent, Pacific Ag/Sunnyside RNG, that the project would generate millions in tax dollars. There was no analysis of costs to tax payers in the form of subsidies, wear and tear on roadways, and decreased property values.

The City of Sunnyside did not *integrate the requirements of SEPA with existing agency planning and licensing procedures and practices, so that such procedures run concurrently rather than consecutively.* Instead Sunnyside issued an MDNS and then told FOTC that we could not appeal the MDNS until a later time after Pacific Ag applied for a permit.

The City of Sunnyside did not *encourage public involvement.* Instead, the city made it difficult for the public to be involved by not posting notices in newspapers, by not translating notices into Spanish, by only notifying about 20 neighbors of the SEPA review, by posting signs in a corn field, by not providing informational paperwork, by refusing to answer questions about the project, and by failure to attend a public meeting regarding the digester on November 30, 2023.

The City of Sunnyside did not *identify reasonable alternatives*, such as on-farm digesters, a more remote location, limitations on hours for manure transport, different methods of manure management and disposal, or the "no-action" alternative.

WAC 197-11-055
Timing of the SEPA Process

*(b) Agencies shall identify the times at which the environmental review shall be conducted either in their procedures or on a case-by-case basis. Agencies may also organize environmental review in phases, as specified in WAC **197-11-060**(5).*

---

[6] See Monitoring Wells LYV-PS-031, LYV-PS-032, and LYV-PS-033 on Ecology's Environmental Information Monitoring Data Base at https://apps.ecology.wa.gov/eim/search/Groundwater/GWSearchResults.aspx?ResultType=GroundwaterWellTab&StudyUserIds=MRED&StudyUserIdSearchType=Contains&LocationCounties=Yakima&HasGroundwaterData=True

The City of Sunnyside did not state that the environmental review for the Sunnyside RNG project would be organized in phases.

*(c) Appropriate consideration of environmental information shall be completed before an agency commits to a particular course of action (WAC **197-11-070**).*

The Port of Sunnyside committed to the Sunnyside RNG project by proposing the sale of property to Pacific AG in November 2022.[7] The City of Sunnyside issued a determination of non-significance for that sale on December 6, 2022.[8] Sale of real estate for a designated purpose is a commitment to a course of action.

Notice of the sale was not properly advertised. Public comments regarding the sale have not been posted. The City of Sunnyside approved an MDNS for the Sunnyside RNG project on June 22, 2023, six months after sale approval.

*(4) **Applicant review at conceptual stage.** In general, agencies should adopt procedures for environmental review and for preparation of EISs on private proposals at the conceptual stage rather than the final detailed design stage.*[9]

(a) If an agency's only action is a decision on a building permit or other license that requires detailed project plans and specifications, agencies shall provide applicants with the opportunity for environmental review under SEPA prior to requiring applicants to submit such detailed project plans and specifications.

*(b) Agencies may specify the amount of detail needed from applicants for such early environmental review, consistent with WAC **197-11-100** and **197-11-335**, in their SEPA or permit procedures.*

(c) This subsection does not preclude agencies or applicants from preliminary discussions or exploration of ideas and options prior to commencing formal environmental review.

On November 30, 2023, Harrison Pettit from Pacific AG told attendees at a public meeting regarding the Sunnyside RNG project that conversations regarding the project have been ongoing for two years. The fact that the Port of Sunnyside sold property to Pacific Ag for the project indicates a commitment on the part of the Port of Sunnyside and the City of Sunnyside to the biodigester project.

There is no documentation of alternatives as addressed in RCW 43.21C.030(2)(c)(iii), RCW 43.21C.030(2)(e), WAC 197-11-030(2), WAC 197-11-060 (1), WAC 197-11-060

---

[7] Port of Sunnyside Property Sale. http://www.friendsoftoppenishcreek.org/cabinet/data/AVS%203%20SS%20RNG%20Property%20Sale%20Notice.pdf

[8] DNS for Property Sale. http://www.friendsoftoppenishcreek.org/cabinet/data/SS%20RNG%20DNS_SEPA-2022.0046.pdf

[9] FOTC assumed in July of 2023 that the Sunnyside RNG project is a public and private partnership, based on statements in the June 22, 2023, MDNS. However, at a November 30, 2023 public meeting regarding the project, Harrison Pettit from Pacific Ag stated several times that this is a private project.

(2), WAC 197-11-060 (3), WAC 197-11-080(1), WAC 197-11-400 (2), WAC 197-11-402(1), WAC 197-11-402(9), WAC 197-11-408(2), WAC 197-11-440(4), WAC 197-11-440(5), WAC 197-11-655(3). According to WAC 197-11-440(5)(b)(ii) *The "no-action" alternative shall be evaluated and compared to other alternatives.*

*(5) An overall decision to proceed with a course of action may involve a series of actions or decisions by one or more agencies. If several agencies have jurisdiction over a proposal, they should coordinate their SEPA processes wherever possible. The agencies shall comply with lead agency determination requirements in WAC **197-11-050** and **197-11-922**.*

(6) To meet the requirement to insure that environmental values and amenities are given appropriate consideration along with economic and technical considerations, environmental documents and analyses shall be circulated and reviewed with other planning documents to the fullest extent possible.

Selected environmental documents for the Sunnyside RNG project were first shared with the public on May 23, 2023. A Traffic Impact Analysis was not published until July of 2023. There is still no approved air study. Questions regarding increased pollution related to the production of manure to feed the digester, and emissions from the digestate produced by the digester have not been answered.

WAC 197-11-060 (4) Impacts.

*(a) SEPA's procedural provisions require the consideration of "environmental" impacts (see definition of "environment" in WAC **197-11-740** and of "impacts" in WAC **197-11-752**), with attention to impacts that are likely, not merely speculative. (See definition of "probable" in WAC **197-11-782** and **197-11-080** on incomplete or unavailable information.)*

*(b) In assessing the significance of an impact, a lead agency shall not limit its consideration of a proposal's impacts only to those aspects within its jurisdiction, including local or state boundaries (see WAC **197-11-330**(3) also).*

(c) Agencies shall carefully consider the range of probable impacts, including short-term and long-term effects. Impacts shall include those that are likely to arise or exist over the lifetime of a proposal or, depending on the particular proposal, longer.

(d) A proposal's effects include direct and indirect impacts caused by a proposal. Impacts include those effects resulting from growth caused by a proposal, as well as the likelihood that the present proposal will serve as a precedent for future actions. For example, adoption of a zoning ordinance will encourage or tend to cause particular types of projects or extension of sewer lines would tend to encourage development in previously unsewered areas.

*(e) The range of impacts to be analyzed in an EIS (direct, indirect, and cumulative impacts, WAC **197-11-792**) may be wider than the impacts for which mitigation measures are required of applicants (WAC **197-11-660**). This will depend upon the specific impacts, the extent to which the adverse impacts are attributable to the applicant's proposal, and the capability of applicants or agencies to control the impacts in each situation.*

This is a large project. This bio-digester may be one of the largest in the United States. Impacts will extend beyond the Sunnyside City Limits.

- There will be increased traffic on Yakima County roads to haul manure and crop residues to the digester, to haul digestate from the digester, to haul composted digestate to markets. Increased traffic brings increased pollution of the air with nitrogen oxides and particulate matter. Increased traffic brings increased wear and tear on county roads and costs to tax payers across the county. FOTC submitted an evaluation of the Sunnyside RNG TIA to Yakima County and the Port of Sunnyside on August 28, 2023.[10] We await responses.
- If dairies receive up to $200 per year per cow for manure, there is an incentive to increase the number of cows in each herd. More cows mean increased leaching to the aquifers, and increased air emissions. More cows mean more land taken out of production of fruits and vegetables and more land devoted to dairies and cattle feed. Corn and alfalfa, the major crops for cattle feed, require large amounts of water. Corn is hard on the land, requires large amounts of fertilizer and introduces a wide range of plant pathogens.
- FOTC does not believe it is possible to test for and screen out all the possible contaminants in digestate. There is a significant risk of spreading pathogens to a large number of farming operations when digestate is spread as fertilizer or used as animal bedding. For example, cryptosporidium is a common and wide spread zoonotic parasite that attacks young calves and is more common on dairies with intense confinement and moist conditions.[11] If there is cryptosporidium in manure used as feedstock, the parasite may proliferate in the digesters, live in the digestate, and infect soils for miles around where farmers spread digestate. Cryptosporidium could infect large numbers of animals housed in facilities that use the digestate for bedding.
- If dairies receive up to $200 per year per cow for manure, the up to 25 LYV dairies that participate in this project have a serious economic advantage over the 15 or more dairies that do not. If a dairy has 1,000 milk cows and receives $200 per year per cow, that dairy will increase annual income by $200,000. This makes a difference in which dairies survive and which do not.
- Sunnyside RNG has not described contracts with dairies. FOTC believes there is a potential for this project to squeeze out non-participating dairies and to create dairy dependence on the digester for economic survival. If dependence occurs, then LYV dairies are at the mercy of digester operators who can raise or lower the rates of payment for manure. There is a troubled dairy digester in Iowa where

[10] See Attachment 4

[11] Oregon State University. The cryptosporidium parasite and its effect on calves and humans. https://extension.oregonstate.edu/animals-livestock/beef/cryptosporidium-parasite-its-effect-calves-humans *Cryptosporidium is* most infectious when the parasite is passed in feces and then ingested. Infected calves can have crypto in their feces for weeks after they are no longer sick.
Crypto eggs have a tough outer shell and are resistant to disinfectants, even chlorine bleach. They can survive outside the body and in the environment for long periods. The eggs can be killed by generous applications of a 3% hydrogen peroxide solution as well as exposure to high temperatures in excess of 160° F, which is hotter than most domestic tap water.

economic benefits do not pencil out. A recent newspaper article[12] about the Waunakee Digester in Wisconsin stated:

Many of the assumptions the company made at the start were wrong. In the future, the business model will have to be tweaked, and farmers sending manure to comparable operations may need to pay the plant to accept it.

- Regarding global warming: To our knowledge no one has calculated how much diesel fuel would be burned to transport manure and digestate for this project.
- Regarding global warming: Dairies produce at least one metric ton of CO_2 equivalents via enteric fermentation for every metric ton of methane produced in anaerobic manure lagoons. Consider a hypothetical community that produces 0.5 MMT CO_2 equivalents of methane via enteric fermentation, and 0.5 MMT CO_2 equivalents of methane from manure lagoons. This equals 1 MMT CO_2 equivalents of methane total. Suppose the community can process all the methane from manure lagoons into renewable natural gas. The total is now 0.5 MMT CO_2 equivalents of methane. Because the operation is profitable the community doubles the number of cows. All the methane from manure lagoons is captured, but the community now produces 1 MMT CO_2 equivalents of methane from enteric fermentation – back to the starting point. Plus the emission of other air pollutants has doubled & emissions from manure transport has doubled, etc.
- We do not see an accounting of how much income for the proposed digester comes from the Washington Cap and Trade program, and from tax payers. The Cap and Trade program does not last forever. Can the Sunnyside RNG digester continue to profit if subsidies decline?
- According to the EPA AgStar program[13] there are many ways to reduce methane emissions from livestock manure management. Some methods are:
    - *Anaerobic digesters – 50% reduction*
    - *Daily spread – 45% reduction*
    - *Pasture based management – 45% reduction*
    - *Composting – 45% reduction*
    - *Solid storage – 45% reduction*
    - *Manure drying practices – 45% reduction*
    - *Semi-permeable covers – 40% reduction*
    - *Decreased manure storage time – 40% reduction*
    - *Composted bedded pack barns – 30% reduction*
    - *Solid separation of manure solids prior to entry to wet/anaerobic environment – 20% reduction*

  But anaerobic digesters cost so much more than the other methods.

[12] State-financed manure digester plagued by spills, explosions. 2015. https://archive.jsonline.com/news/statepolitics/state-financed-manure-digester-plagued-by-spills-explosion-b99435123z1-290263421.html

[13] EPA AgStar. (2023) Practices to Reduce Methane Emissions from Livestock Manure Management. https://www.epa.gov/agstar/practices-reduce-methane-emissions-livestock-manure-management

- The Sunnyside RNG New Source Review (NSR) application requires more information and does not quantify the amount of air pollutants currently in the LYV ambient air. It does not estimate the percentage of air pollution attributable to the proposed Sunnyside RNG digester if it becomes reality. Would Sunnyside residents be forced to stop using wood stoves to compensate for digester emissions to keep Yakima County in compliance with U.S. criteria air standards?
- There are significant increases in morbidity and mortality associated with fine particulate air pollution.[14] One study found a decrease of 10 $\mu g/m^3$ of fine particulate concentration was associated with an estimated increase in life expectancy equal to 0.77 years.[15] By how much would fine particulate matter levels increase in the LYV if the Sunnyside RNG digester were built? What is the cost of human health and life?

WAC 197-11-060 Content of Environmental Review

(5) ***Phased review.***

(a) Lead agencies shall determine the appropriate scope and level of detail of environmental review to coincide with meaningful points in their planning and decision-making processes. (See WAC ***197-11-055*** *on timing of environmental review.)*

(b) Environmental review may be phased. If used, phased review assists agencies and the public to focus on issues that are ready for decision and exclude from consideration issues already decided or not yet ready. Broader environmental documents may be followed by narrower documents, for example, that incorporate prior general

[15] Pope CA 3rd, Ezzati M, Dockery DW. Fine-particulate air pollution and life expectancy in the United States. N Engl J Med. 2009 Jan 22;360(4):376-86. doi: 10.1056/NEJMsa0805646. PMID: 19164188; PMCID: PMC3382057. https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3382057/

discussion by reference and concentrate solely on the issues specific to that phase of the proposal.

(c) Phased review is appropriate when:

*(i) The sequence is from a nonproject document to a document of narrower scope such as a site specific analysis (see, for example, WAC **197-11-443**); or*

(ii) The sequence is from an environmental document on a specific proposal at an early stage (such as need and site selection) to a subsequent environmental document at a later stage (such as sensitive design impacts).

(d) Phased review is not appropriate when:

(i) The sequence is from a narrow project document to a broad policy document;

(ii) It would merely divide a larger system into exempted fragments or avoid discussion of cumulative impacts; or

*(iii) It would segment and avoid present consideration of proposals and their impacts that are required to be evaluated in a single environmental document under WAC 197-11-060 (3)(b) or **197-11-305**(1); however, the level of detail and type of environmental review may vary with the nature and timing of proposals and their component parts.*

(e) When a lead agency knows it is using phased review, it shall so state in its environmental document.

(f) Agencies shall use the environmental checklist, scoping process, nonproject EISs, incorporation by reference, adoption, and supplemental EISs, and addenda, as appropriate, to avoid duplication and excess paperwork.

*(g) Where proposals are related to a large existing or planned network, such as highways, streets, pipelines, or utility lines or systems, the lead agency may analyze in detail the overall network as the present proposal or may select some of the future elements for present detailed consideration. Any phased review shall be logical in relation to the design of the overall system or network, and shall be consistent with this section and WAC **197-11-070**.*

The City of Sunnyside did not state that the city would use a phased review. FOTC believes the City of Sunnyside should have gathered information sooner and presented all relevant environmental information with the initial SEPA review. Because the process now involves addressing a SEPA Review and then addressing Addenda to the SEPA review, the amount of study and paperwork has doubled, at least for FOTC.

WAC 197-11-080

Incomplete or unavailable information.

(1) If information on significant adverse impacts essential to a reasoned choice among alternatives is not known, and the costs of obtaining it are not exorbitant, agencies shall obtain and include the information in their environmental documents.

(2) When there are gaps in relevant information or scientific uncertainty concerning significant impacts, agencies shall make clear that such information is lacking or that substantial uncertainty exists.

(3) Agencies may proceed in the absence of vital information as follows:

(a) If information relevant to adverse impacts is essential to a reasoned choice among alternatives, but is not known, and the costs of obtaining it are exorbitant; or

(b) If information relevant to adverse impacts is important to the decision and the means to obtain it are speculative or not known;

Then the agency shall weigh the need for the action with the severity of possible adverse impacts which would occur if the agency were to decide to proceed in the face of uncertainty. If the agency proceeds, it shall generally indicate in the appropriate environmental documents its worst case analysis and the likelihood of occurrence, to the extent this information can reasonably be developed.

*(4) Agencies may rely upon applicants to provide information as allowed in WAC **197-11-100**.*

The City of Sunnyside did not document incomplete information, as required in the rule. FOTC believes that significant information is missing, and this should have been documented. See the concerns described on pages 6 to 9 above. We are especially concerned about costs to tax payers, impact on non-participating dairies and other farms, spreading disease, unknown increases in LYV air pollution, wear and tear on county roads, increases in traffic accidents, dangers to school children, and risks of fire and explosions.

Although the chances of fires and explosions are not great, damage when such incidents occur may be high and could include death.[16] A quality SEPA review must acknowledge this risk and address it. See WAC 197-11-794 (2).

The Sunnyside RNG SEPA Check list says:

Anaerobic-digestor-based renewable natural gas facilities produce biogas composed of methane (CH4) which is a flammable gas (under limited circumstances), hydrogen sulfide (H2S) which is both a flammable and toxic gas, along with CO2 and vocs. These components will be contained in anaerobic tanks with membrane roofs and in the downstream raw biogas piping systems designed in compliance with industry standards for sour gas facilities.

Methane (CH4) and Hydrogen Sulfide (H2S) are products of the anaerobic digestion process and both are considered hazardous with H2S also considered toxic. Both components will be present in the facility tanks and piping. Their hazardous and/or toxic characteristics along with response measures, should either be released to the atmosphere, can be found in Safety Data Sheets (SDS). Process chemicals such as solvents, oils, lubricants, antifreeze, ferric chloride and natural gas injection calibration gases such as Nitrogen, Propane, Helium, and potentially odorant will be used in limited quantities.

Standard emergency and fire services, as well as potentially confined space rescue. Other special health and safety planning is underway and will be confirmed with emergency

[16] See Attachment 2

services and County Health Department. Standard emergency services equipment includes self-contained breathing apparatus (SCBA) appropriate for potential exposure.

The following measures may be implemented to reduce or control environmental health hazards: A health and safety plan would be followed during construction to address worker safety and to minimize exposure to potential environmental health hazards. To help detect potential leaks quickly, an odorant may be added to the gas . Pressure and flow at the facilities will be monitored to ensure proper operation and reduce potential risk for fire and explosion. The centralized gas cleaning unit would be designed with internal shutoff valves that will switch automatically if the system detects a malfunction. The centralized gas cleaning unit would be outfitted with control technology to ensure that emissions are below the acceptable source impact level for air pollutants associated with project operation. The extremely limited areas where toxic/ hazardous materials are utilized will have impermeable surfaces and curbing to contain any potential spills.

Every methane producing facility with spills, leaks, fires, and explosions said the same things when they convinced communities to permit operations. Nothing in this statement is enforceable.[17]

The checklist says, *The following measures <u>may be implemented</u> to reduce or control environmental health hazards.*

If there is an accident and victims argue for compensation, Sunnyside RNG insurance companies can simply say, 'W never promised to do those things. We said those measures *may be implemented*.'

A useful SEPA check list would tell the reader, among other things:

- Where on the facility would alarms and monitors be located?
- What would be the pressure and flow danger signs?
- Would monitoring be automated or by trained personnel?
- What would the alarms detect?
- Frequency of alarm checks to make sure they function properly?
- How would the facility check for corrosion in the piping system, in the tank floors and walls?
- How often would piping be checked for leaks?
- When would equipment be replaced as the facility ages?
- Required safety training for staff – content, how often?
- Evacuation routes?
- What are protocols for rescuing trapped and endangered workers?
- Would there be monitoring for release of pathogens in effluent and air?
- Would there be fenceline monitoring?

[17] The City of Sunnyside Municipal Code 18.04.120.E.3 states: *The applicant's proposed mitigation measures must be in writing and must be specific. For example, proposals to "control noise" or "prevent storm water runoff" are inadequate, whereas proposals to "muffle machinery to X decibels" or "construction 200-foot storm water retention pond at Y location" are adequate.*

- What are proposed protocols for notifying neighbors of leaks and dangers?
- Describe a worst case scenario for fires and explosions

WAC 197-11-158 SEPA/GMA project review—Reliance on existing plans, laws, and regulations.

*(1) In reviewing the environmental impacts of a project and making a threshold determination, a GMA county/city may, at its option, determine that the requirements for environmental analysis, protection, and mitigation measures in the GMA county/city's development regulations and comprehensive plan adopted under chapter **36.70A** RCW, and in other applicable local, state, or federal laws or rules, provide adequate analysis of and mitigation for some or all of the specific adverse environmental impacts of the project.*

(2) In making the determination under subsection (1) of this section, the GMA county/city shall:

*(d) Place the following statement in the threshold determination if all of a project's impacts are addressed by other applicable laws and no conditions will be required under SEPA: "The lead agency has determined that the requirements for environmental analysis, protection, and mitigation measures have been adequately addressed in the development regulations and comprehensive plan adopted under chapter **36.70A** RCW, and in other applicable local, state, or federal laws or rules, as provided by RCW **43.21C.240** and WAC 197-11-158. Our agency will not require any additional mitigation measures under SEPA."*

The City of Sunnyside did not select this option.

WAC 197-11-164 Planned actions—Definition and criteria.

*(1) Under RCW **43.21C.440**, GMA counties/cities may designate a planned action.*

FOTC interpretation is that the Sunnyside RNG project is not a planned action.

WAC 197-11-330 Threshold determination process.

*(3) In determining an impact's significance (WAC **197-11-794**), the responsible official shall take into account the following, that:*

(a) The same proposal may have a significant adverse impact in one location but not in another location;

(b) The absolute quantitative effects of a proposal are also important, and may result in a significant adverse impact regardless of the nature of the existing environment;

(c) Several marginal impacts when considered together may result in a significant adverse impact;

(d) For some proposals, it may be impossible to forecast the environmental impacts with precision, often because some variables cannot be predicted or values cannot be quantified.

(e) A proposal may to a significant degree:

(i) Adversely affect environmentally sensitive or special areas, such as loss or destruction of historic, scientific, and cultural resources, parks, prime farmlands, wetlands, wild and scenic rivers, or wilderness;

(ii) Adversely affect endangered or threatened species or their habitat;

(iii) Conflict with local, state, or federal laws or requirements for the protection of the environment; and

(iv) Establish a precedent for future actions with significant effects, involves unique and unknown risks to the environment, or may affect public health or safety.

*(4) If after following WAC **197-11-080** and **197-11-335** the lead agency reasonably believes that a proposal may have a significant adverse impact, an EIS is required.*

(5) A threshold determination shall not balance whether the beneficial aspects of a proposal outweigh its adverse impacts, but rather, shall consider whether a proposal has any probable significant adverse environmental impacts under the rules stated in this section. For example, proposals designed to improve the environment, such as sewage treatment plants or pollution control requirements, may also have significant adverse environmental impacts.

Many people believe that the SS RNG digester should be located away from the City of Sunnyside, in a more remote area.

People note that the proposed digester will be situated near the Windmill Mushroom Farms that already sends odorous emissions into the ambient air, and the Nutrien Fertilizer Plant with a history of a fire that required evacuation of neighbors, and the Sunnyside wastewater treatment plant that sprays odorous effluent onto nearby fields.

The proposed digester would be near the area where the poorer people of Sunnyside live and farther from more affluent areas. A previous site, near more affluent areas, and near the Williams natural gas pipeline, was rejected. No one is stating the reason.

Soil at this site, Quincy loamy fine sand, is “excessively drained” according to the Natural Resources Conservation Service. Nearby monitoring wells at the Port of Sunnyside show high levels of nitrates in the underlying aquifer. Sunnyside RNG has not stated what kind of liner will be used for digester lagoons. It is reasonable to expect that spills on the digester site would quickly leach to the aquifer.

Approval of this project without an Environmental Impact Statement would demonstrate to the public that Washington laws to protect people in marginalized neighborhoods mean nothing.

197-11-335 Additional information.

*The lead agency shall make its threshold determination based upon information reasonably sufficient to evaluate the environmental impact of a proposal (WAC **197-11-055**(2) and **197-11-060**(3)). The lead agency may take one or more of the following actions if, after reviewing the checklist, the agency concludes that there is insufficient information to make its threshold determination:*

(1) Require an applicant to submit more information on subjects in the checklist;

(2) Make its own further study, including physical investigations on a proposed site;

*(3) Consult with other agencies, requesting information on the proposal's potential impacts which lie within the other agencies' jurisdiction or expertise (agencies shall respond in accordance with WAC **197-11-550**); or*

*(4) Decide that all or part of the action or its impacts are not sufficiently definite to allow environmental analysis and commit to timely, subsequent environmental analysis, consistent with WAC **197-11-055** through **197-11-070**.*

There is insufficient information in the Sunnyside RNG checklist to evaluate the environmental impact of the proposed digester.

- Only vague speculation about project expansion
- A Geotechnical Report and Phase I ESA are referenced but not available for review
- There is no air permit. The application posted on the City of Sunnyside web site that appears to have been accepted by the Yakima Regional Clean Air Agency was not in fact accepted. The YRCAA returned it to Sunnyside RNG for more information
- Could the answers be any vaguer? How about this: "Best management practices will be used to reduce and control erosion. Local and state laws will be followed. Silt fence, construction entrance, an inlet protection are planned."[18]
- The Environmental Checklist assures the public that emissions from the proposed digester will not exceed:
    - CO - 100 tons per year (tpy)
    - NOX - 40 tons per year (tpy)
    - SO2 - 40 tons per year (tpy)
    - PM - 25 tons per year (tpy)
    - PM10-15tpy
    - PM25 -10 tpy

[18] The City of Sunnyside Municipal Code 18.04.120.E.3 states: *The applicant's proposed mitigation measures must be in writing and must be specific. For example, proposals to "control noise" or "prevent storm water runoff" are inadequate, whereas proposals to "muffle machinery to X decibels" or "construction 200-foot storm water retention pond at Y location" are adequate.*

Suppose the SS RNG digester only emits 5 tons per year of PM 2.5, fine particulate matter, and Windmill Mushroom Farms only emits 5 tons per year of fine particulate matter, and Nutrien Solutions only emits 5 tons per year of fine particulate matter, and the City of Sunnyside Waste Water Treatment Plant only emits 5 tons per year of fine particulate matter. The Total is 20 tons per year. What does this mean for South Sunnyside air quality? Wouldn't it be better to study this problem before ground is broken, rather than trying to protect human health with home air filters and breathing treatments afterwards?

- *Stormwater runoff will be retained on site and infiltrated into the ground at various locations including a potential stormwater pond. This water will not flow into other waters.* This means that stormwater will wash spilled manure and digestate from the site into the ground. Who will monitor for onsite spills? Is groundwater monitoring appropriate here?
- *Natural gas used for heat (the boilers) is accounted for in the air emissions as well as avoided methane calculations.* This natural gas should not be counted in avoided methane calculations.
- *Thermal energy will be recaptured from the amine re boiler for heating other site processes. Where appropriate variable rate pumps will be used.* There is insufficient information to quantify these proposed savings. There is insufficient information for the average reader, including City of Sunnyside Officials, to understand the nature of an amine boiler.
- *To help detect potential leaks quickly, an odorant may be added to the gas*. An odorant "may" be added. You "may" win the lottery
- *Noise is not anticipated to be a problem*. Please tell us why not.
- FOTC's table top calculation, using data from the SS RNG Traffic Impact Analysis estimates there will be an additional 1,500 miles of truck traffic per day mostly on Yakima County Roads. Heavy duty trucks inflict about 2,500 times more wear and tear on roads than private cars. There is no estimate of cost to maintain the impacted county roads.

WAC 197-11-340 Determination of nonsignificance (DNS).

(2)(c) Any person, affected tribe, or agency may submit comments to the lead agency within fourteen days of the date of issuance of the DNS.
(2)(f) The responsible official shall reconsider the DNS based on timely comments and may retain or modify the DNS or, if the responsible official determines that significant adverse impacts are likely, withdraw the DNS or supporting documents. When a DNS is modified, the lead agency shall send the modified DNS to agencies with jurisdiction.
(3)(a) The lead agency shall withdraw a DNS if:

(i) There are substantial changes to a proposal so that the proposal is likely to have significant adverse environmental impacts;

(ii) There is significant new information indicating, or on, a proposal's probable significant adverse environmental impacts; or

(iii) The DNS was procured by misrepresentation or lack of material disclosure; if such DNS resulted from the actions of an applicant, any subsequent environmental

checklist on the proposal shall be prepared directly by the lead agency or its consultant at the expense of the applicant.

(b) Subsection (3)(a)(ii) shall not apply when a nonexempt license has been issued on a private project.

*(c) If the lead agency withdraws a DNS, the agency shall make a new threshold determination and notify other agencies with jurisdiction of the withdrawal and new threshold determination. If a DS is issued, each agency with jurisdiction shall commence action to suspend, modify, or revoke any approvals until the necessary environmental review has occurred (see also WAC **197-11-070**).*

The City of Sunnyside issued a mitigated determination of non-significance (MDNS) of the SS RNG project on June 22, 2023.

The Friends of Toppenish Creek submitted an appeal of the MDNS on July 6, 2023.[19]

There is no evidence that the responsible official reconsidered the MDNS based on FOTC's lengthy comments, as required by WAC 197-11-340(2)(f).

FOTC maintains there was a lack of material disclosure due to the absence of data regarding air quality, risks for fires and explosion, and traffic impacts. The agency with expertise for air, the YRCAA, did not comment. A Traffic Impact Analysis (TIA) was not available for review prior to our July 6, 2023 appeal.

WAC 197-11-350 Mitigated DNS.

The purpose of this section is to allow clarifications or changes to a proposal prior to making the threshold determination.

(1) In making threshold determinations, an agency may consider mitigation measures that the agency or applicant will implement.

(2) After submission of an environmental checklist and prior to the lead agency's threshold determination on a proposal, an applicant may ask the lead agency to indicate whether it is considering a DS. If the lead agency indicates a DS is likely, the applicant may clarify or change features of the proposal to mitigate the impacts which led the agency to consider a DS likely. The applicant shall revise the environmental checklist as may be necessary to describe the clarifications or changes. The lead agency shall make its threshold determination based upon the changed or clarified proposal. If a proposal continues to have a probable significant adverse environmental impact, even with mitigation measures, an EIS shall be prepared.

(3) Whether or not an applicant requests early notice under subsection (2), if the lead agency specifies mitigation measures on an applicant's proposal that would allow it to issue a DNS, and the proposal is clarified, changed, or conditioned to include those measures, the lead agency shall issue a DNS.

[19] See Attachment 2

(4) Environmental documents need not be revised and resubmitted if the clarifications or changes are stated in writing in documents that are attachments to, or incorporate by reference, the documents previously submitted. An addendum may be used, see Part Six.

The June 22, 2023 MDNS for the SS RNG project stated the following mitigation measures:

Mitigation Measure: An Inadvertent Discovery Plan shall be created and submitted to the City of Sunnyside as part of the building permit package for the prosed development.

Mitigating Measures: a stormwater management plan is required to be submitted for review and approval by City of Sunnyside public works department prior to construction. The plan must meet the following design standards:

a) Stormwater retention or detention shall be provided. A professional engineer registered in the state of Washington shall design all drainage facilities and components. Drainage plans using best management practices and design requirements must be submitted to and approved by City of Sunnyside prior to grading or development.
b) Post development stormwater flow rates and volumes shall not exceed predevelopment conditions. The standard of full retention of the 25-year storm event generally meets the goal.
c) The depth to groundwater should be determined prior to planning the layout of stormwater facilities. If a stormwater infiltration facility will be used for the disposal of runoff, a permeability test should be conducted initially at the site to determine existing infiltration rates prior to the design stage.

Mitigation Measure: Dust a. A dust control plan must be filed with the Yakima Regional Clean Air Authority.

Documentation for most of these mitigation measures is still missing, namely there is no:

- Inadvertent Discovery Plan, although the addendum letter from SS RNG claims one exists
- NPDES Construction Stormwater permit, although the addendum letter from SS RNG claims one exists
- Stormwater Pollution Prevention Plan, although the addendum letter from SS RNG claims one exists
- Consultation with the WA State Dept. of Ecology and the Yakima Health District regarding a Notice of Intent to operate under terms and conditions of a solid waste permit
- Depth to groundwater and permeability tests

On December 4, 2023, FOTC submitted a public records request to Yakima County Emergency Services for information re conversations with Sunnyside RNG regarding possible fires and explosions. On December 5, 2023, Yakima County Emergency

Services informed FOTC that they have no records of conversations with Pacific Ag/Sunnyside RNG regarding the proposed manure bio-digester.

FOTC interprets this to mean that project proponents have not adequately prepared for possible fires and explosions at the site. There is abundant information demonstrating the possibility of fires and explosions related to methane production facilities.

WAC 197-11-355 Optional DNS process.

In the City of Sunnyside's May 23, 2023 Notice of Environmental Review the city stated:

NOTICE OF ENVIRONMENTAL REVIEW This is to notify agencies with jurisdiction and environmental expertise and the public that the City of Sunnyside, Planning Division, has been established as the lead agency, under WAC § 197-11-928 for this project. The City of Sunnyside has reviewed the proposed project for probable adverse environmental impacts and expects to issue a Determination of Nonsignificance (DNS) per WAC § 197-11-355. The proposal may include mitigation measures under applicable codes and the project review process may incorporate or require mitigation measures regardless of whether an EIS is prepared. A copy of the subsequent threshold determination may be obtained by request and may be appealed pursuant to SMC Ch. 18.04.

However the City of Sunnyside has not incorporated WAC 197-11-355 by reference. See City of Sunnyside Municipal Code, Chapter 18.04 available at https://www.codepublishing.com/WA/Sunnyside/#!/Sunnyside18/Sunnyside1804.html#18.04.020

18.04.080 Categorical exemptions and threshold determinations, provisions adopted by reference.

Regarding the rules for deciding whether a proposal has a "probable significant adverse environmental impact" requiring an EIS to be prepared, and the rules for evaluating the impacts of proposals not requiring an EIS, the City adopts the following sections of Chapter 197-11 WAC by reference:

WAC

197-11-300 Purpose
197-11-305 Categorical Exemptions
197-11-310 Threshold Determination Required
197-11-315 Environmental Checklist
197-11-330 Threshold Determination Process
197-11-335 Additional Information
197-11-340 Determination of Non-Significance

197-11-350 Mitigated Determinations of Non-Significance

197-11-360 Determinations of Significance/Initiation of Scoping

197-11-390 Effects of Threshold Determination

[Ord. 1475 § 2, 1984.]

FOTC questions whether the city can invoke a rule that the city has not approved. The city did not respond when FOTC brought this fact to the city's attention.

WAC 197-11-400 Purpose of EIS.

(1) The primary purpose of an environmental impact statement is to ensure that SEPA's policies are an integral part of the ongoing programs and actions of state and local government.

(2) An EIS shall provide impartial discussion of significant environmental impacts and shall inform decision makers and the public of reasonable alternatives, including mitigation measures, that would avoid or minimize adverse impacts or enhance environmental quality.

(3) Environmental impact statements shall be concise, clear, and to the point, and shall be supported by the necessary environmental analysis. The purpose of an EIS is best served by short documents containing summaries of, or reference to, technical data and by avoiding excessively detailed and overly technical information. The volume of an EIS does not bear on its adequacy. Larger documents may even hinder the decision making process.

(4) The EIS process enables government agencies and interested citizens to review and comment on proposed government actions, including government approval of private projects and their environmental effects. This process is intended to assist the agencies and applicants to improve their plans and decisions, and to encourage the resolution of potential concerns or problems prior to issuing a final statement. An environmental impact statement is more than a disclosure document. It shall be used by agency officials in conjunction with other relevant materials and considerations to plan actions and make decisions.

An Environmental Impact Statement, as described in WAC 197-11-400 is essential for quality decision making. A project as large as the Sunnyside RNG digester should not proceed without study of environmental information at this level

WAC 197-11-500 Purpose of this part.

This part provides rules for:

(1) Notice and public availability of environmental documents, especially environmental impact statements;

(2) Consultation and comment by agencies and members of the public on environmental documents;

(3) Public hearings and meetings; and

(4) Lead agency response to comments and preparation of final environmental impact statements. Review, comment, and responsiveness to comments on a draft EIS are the focal point of the act's commenting process because the DEIS is developed as a result of scoping and serves as the basis for the final statement.

This section especially addresses public notice for Environmental Impact Statements, but it is not limited to EIS. FOTC believes that this section also addresses Environmental Review in sections that do not limit discussion to EIS.

WAC 197-11-502 Inviting comment.

(1) Agency efforts to involve other agencies and the public in the SEPA process should be commensurate with the type and scope of the environmental document.

*(2) Consulted agencies have a responsibility to respond in a timely and specific manner to requests for comments (WAC **197-11-545**, **197-11-550**, and **197-11-724**).*

The Yakima Regional Clean Air Agency, the agency tasked with enforcing the Clean Air Act in Yakima County, did not respond to the City of Sunnyside's request for comments on the May 2023 Notice of Environmental Review. Consequently the MDNS did not contain sufficient analysis of related air impacts. If there were an adequate analysis of air impacts the City of Sunnyside might have issued a Determination of Significance that would have changed the course of these actions.

*(3) **Threshold determinations.***

*(a) Agencies shall send DNSs to other agencies with jurisdiction, if any, as required by WAC **197-11-340**(2) and **197-11-355**.*

The City of Sunnyside has never incorporated WAC 197-11-355 by reference.

*(b) For DNSs issued under WAC **197-11-340**(2), agencies shall provide public notice under WAC **197-11-510** and receive comments on the DNS for fourteen days.*

The City of Sunnyside provided public notice of the MDNS on June 22, 2023, and stated

Appeal Period: This MDNS is issued under WAC 197-11-340(2). The Lead Agency will not act on this proposal for 14 days from the date of issuance. Appeals may be submitted on this proposal to the address below.

However the May 2023 Notice of Environmental Review stated

The City of Sunnyside has reviewed the proposed project for probable adverse environmental impacts and expects to issue a Determination of Nonsignificance (DNS) per WAC § 197-11-355.

FOTC did appeal the MDNS on July 6, 2023. The City of Sunnyside scheduled a hearing date for August 23, 2023. The City of Sunnyside cancelled the hearing on August 16, 2023. The city did not put the cancellation in an official document, but relied instead on an email that said:

After consultation with the City's legal team, it has been discovered that the Mitigated Determination of Nonsignificance (MDNS) issued on June 22, 2023, cannot at this time be appealed. The reason the MDNS cannot be appeal is because the MDNS only serves as an advisory statement on behalf of the City. In order to process an appeal, the MDNS is required to be tied to a development permits, such as a land use review, engineering permit, or building permit. None of those items have been issued for the site at this time, therefore the City cannot process a standalone MDNS appeal. See - Ellensburg Cement Products, Inc. v. Kittitas County, 179 Wn.2d 737 (2014).

FOTC disputed the cancellation to no avail. The City of Sunnyside did not cite rules that allow an unelected official to cancel a legally authorized hearing. In fact, the city did not point to any places in WAC 197-11 that might support the cancellation. It is inappropriate for the city to cite case law as though issuing a ruling from the bench.

FOTC disagrees with the statement *the MDNS only serves as an advisory statement on behalf of the City.* FOTC contends that environmental review means *Deciding whether a proposal has a probable significant adverse impact and thus requires an EIS (the threshold determination)* WAC 197-11-300(2)

(6) ***Public hearings and meetings.***

(a) Public hearings or meetings may be held (WAC ***197-11-535****). Notice of such public hearings shall be given under WAC* ***197-11-510*** *and may be combined with other agency notice.*

(b) In conjunction with the requirements of WAC ***197-11-510****, notice of public hearings shall be published no later than ten days before the hearing. For nonproject proposals, notice of the public hearing shall be published in a newspaper of general circulation in the general area where the lead agency has its principal offices. For nonproject proposals having a regional or statewide applicability, copies of the notice shall be given to the Olympia bureaus of the Associated Press and United Press International.*

The City of Sunnyside refused to conduct public hearings on this project. As noted, the city cancelled a public hearing of the FOTC appeal. There was no opportunity for the community to learn about risks and benefits related to the SS RNG bio-digester, thus a thwarting of the intent of the law.

WAC 197-11-510 Public notice.

(1) When these rules require notice to be given under this section, the lead agency must use reasonable methods to inform the public and other agencies that an

environmental document is being prepared or is available and that public hearing(s), if any, will be held. The agency may use its existing notice procedures.

Examples of reasonable methods to inform the public are:

(a) Posting the property, for site-specific proposals;

(b) Publishing notice in a newspaper of general circulation in the county, city, or general area where the proposal is located;

(c) Notifying public or private groups with known interest in a certain proposal or in the type of proposal being considered;

(d) Notifying the news media;

(e) Placing notices in appropriate regional, neighborhood, ethnic, or trade journals;

(f) Publishing notice in agency newsletters and/or sending notice to agency mailing lists (either general lists or lists for specific proposals or subject areas); and/or

(g) Mailing or emailing notice to any person, group or agency who has requested notice.

*(2) Each agency shall specify its method of public notice in its SEPA procedures, WAC **197-11-904** and **197-11-906**. If an agency does not specify its method of public notice or does not adopt SEPA procedures, the agency shall use methods (a) and (b) in subsection (1).*

(3) Documents which are required to be sent to the department of ecology under these rules will be published in the SEPA register, which will also constitute a form of public notice. However, publication in the SEPA register shall not, in itself, meet compliance with this section.

FOTC only became aware of the SS RNG MDNS as a result of a public records request. FOTC paid particular attention to public notices in the Yakima Herald Republic because we heard rumors about the proposed digester. We found zero notices in the Yakima Herald Republic or in the Spanish media.

To the best of our knowledge notices were sent to about twenty residences near the proposed site. Many of the recipients only speak Spanish, yet the notices were only in English. This project, if completed will have long lasting impacts on the entire county, yet most people in the county are still unaware.

The City of Sunnyside or the Port of Sunnyside placed a sign in a cornfield at the proposed site next to a highway with a 55 mph speed limit. Public notice was minimal and inadequate.

WAC 197-11-535 Public hearings and meetings.

(1) If a public hearing on the proposal is held under some other requirement of law, such hearing shall be open to consideration of the environmental impact of the proposal, together with any environmental document that is available. This does not require extension of the comment periods for environmental documents.

(2) In all other cases a public hearing on the environmental impact of a proposal shall be held whenever one or more of the following situations occur:

(a) The lead agency determines, in its sole discretion, that a public hearing would assist it in meeting its responsibility to implement the purposes and policies of SEPA and these rules; or

(b) When fifty or more persons residing within the jurisdiction of the lead agency, or who would be adversely affected by the environmental impact of the proposal, make written request to the lead agency within thirty days of issuance of the draft EIS; or

(c) When two or more agencies with jurisdiction over a proposal make written request to the lead agency within thirty days of the issuance of the draft EIS.

*(3) Whenever a public hearing is held under subsection (2) of this section, it shall occur no earlier than fifteen days from the date the draft EIS is issued, nor later than fifty days from its issuance. Notice shall be given under WAC **197-11-502**(6) and **197-11-510** and may be combined with other agency notice.*

(4) If a public hearing is required under this chapter, it shall be open to discussion of all environmental documents and any written comments that have been received by the lead agency prior to the hearing. A copy of the environmental document shall be available at the public hearing.

*(5) Comments at public hearings should be as specific as possible (see WAC **197-11-550**).*

(6) Agencies and their designees may hold informal public meetings or workshops. Such gatherings may be more flexible than public hearings and are not subject to the above notice and similar requirements for public hearings.

*(7) Public meetings held by local governments under chapter **36.70B** RCW may be used to meet SEPA public hearing requirements as long as the requirements for public hearing in this section are met. A public hearing under this section need not be an open record hearing as defined in RCW **36.70B.020**(3).*

Based on WAC 197-11-535(2) & (3) FOTC concludes that this section primarily applies to Environmental Impact Statements. However, the City of Sunnyside could have conducted public meetings or workshops to inform residents about the risks and benefits of this proposed project. Such an action would have demonstrated confidence in the intelligence and civic interest of members of the public. Absence of such meetings indicates a propensity to keep the public in the dark.

WAC 197-11-545 Effect of no comment.

.

*(1) **Consulted agencies.** If a consulted agency does not respond with written comments within the time periods for commenting on environmental documents, the lead agency may assume that the consulted agency has no information relating to the potential impact of the proposal as it relates to the consulted agency's jurisdiction or special expertise. Any consulted agency that fails to submit substantive information to the lead agency in response to a draft EIS is thereafter barred from alleging any defects in the lead agency's compliance with Part Four of these rules.*

*(2) **Other agencies and the public.** Lack of comment by other agencies or members of the public on environmental documents, within the time periods specified by*

*these rules, shall be construed as lack of objection to the environmental analysis, if the requirements of WAC **197-11-510** are met.*

It is extremely disturbing that the Yakima Regional Clean Air Agency and the Yakima Health District did not comment on the SS RNG Environmental Review. This failure to comment borders on failure to fulfill these agencies' mandated duties.

It is impossible to construct a manure methane bio-digester that produces between 800,000 and 950,000 MMBtu's of renewable natural gas per year without an impact on air quality or human health.

WAC 197-11-600 When to use existing environmental documents.

(1) This section contains criteria for determining whether an environmental document must be used unchanged and describes when existing documents may be used to meet all or part of an agency's responsibilities under SEPA.

(2) An agency may use environmental documents that have previously been prepared in order to evaluate proposed actions, alternatives, or environmental impacts. The proposals may be the same as, or different than, those analyzed in the existing documents.

Pacific Ag/Sunnyside RNG acknowledges that the company must acquire an air quality permit prior to commencing construction. When the YRACC evaluates such an application the YRCAA may incorporate the City of Sunnyside's MDNS, even though the YRCAA failed to comment on air impacts. FOTC would interpret such an action as an attempt to circumvent SEPA laws, and permit a polluting operation.

(3) Any agency acting on the same proposal shall use an environmental document unchanged, except in the following cases:

*(a) For DNSs, an agency with jurisdiction is dissatisfied with the DNS, in which case it may assume lead agency status (WAC **197-11-340** (2)(e) and **197-11-948**).*

(b) For DNSs and EISs, preparation of a new threshold determination or supplemental EIS is required if there are:

(i) Substantial changes to a proposal so that the proposal is likely to have significant adverse environmental impacts (or lack of significant adverse impacts, if a DS is being withdrawn); or

(ii) New information indicating a proposal's probable significant adverse environmental impacts. (This includes discovery of misrepresentation or lack of material disclosure.) A new threshold determination or SEIS is not required if probable significant adverse environmental impacts are covered by the range of alternatives and impacts analyzed in the existing environmental documents.

FOTC has introduced new evidence of potential adverse impacts in the forms of 1. an Evaluation of the Sunnyside RNG Traffic Impact Analysis, 2. Documentation of fires and explosions on other manure bio-digesters, 3. Reference to groundwater issues at the Port of Sunnyside, 4. Data supporting likelihood of cumulative impacts, and 5. Demographic data that demonstrates Environmental Justice concerns.

(c) For EISs, the agency concludes that its written comments on the DEIS warrant additional discussion for purposes of its action than that found in the lead agency's FEIS (in which case the agency may prepare a supplemental EIS at its own expense).

(4) Existing documents may be used for a proposal by employing one or more of the following methods:

(a) "Adoption," where an agency may use all or part of an existing environmental document to meet its responsibilities under SEPA. Agencies acting on the same proposal for which an environmental document was prepared are not required to adopt the document; or

(b) "Incorporation by reference," where an agency preparing an environmental document includes all or part of an existing document by reference.

(c) An addendum, that adds analyses or information about a proposal but does not substantially change the analysis of significant impacts and alternatives in the existing environmental document.

(d) Preparation of a SEIS if there are:

(i) Substantial changes so that the proposal is likely to have significant adverse environmental impacts; or

(ii) New information indicating a proposal's probable significant adverse environmental impacts.

New information provided by FOTC, and others strongly indicates significant adverse environmental impacts from the SS RNG project. These impacts may be direct, indirect, short term, long term, widespread and cumulative. An EIS is warranted.

(e) If a proposal is substantially similar to one covered in an existing EIS, that EIS may be adopted; additional information may be provided in an addendum or SEIS (see (c) and (d) of this subsection).

WAC 197-11-655 Implementation.

*(1) See RCW **43.21C.020**, **43.21C.030**(1), **43.21C.060**, **43.21C.075**, and **43.21C.080**.*

(2) Relevant environmental documents, comments, and responses shall accompany proposals through existing agency review processes, as determined by agency practice and procedure, so that agency officials use them in making decisions.

(3) When a decision maker considers a final decision on a proposal:

(a) The alternatives in the relevant environmental documents shall be considered.

(b) The range of alternative courses of action considered by decision makers shall be within the range of alternatives discussed in the relevant environmental documents. However, mitigation measures adopted need not be identical to those discussed in the environmental document.

(c) If information about alternatives is contained in another decision document which accompanies the relevant environmental documents to the decision maker, agencies are encouraged to make that information available to the public before the decision is made.

Since the City of Sunnyside did not evaluate alternatives to the SS RNG proposal, the city cannot comply with WAC 197-11-655

WAC 197-11-680 Appeals.

(1) ***Introduction.*** *Appeals provisions in SEPA are found in RCW* ***43.21C.060****,* ***43.21C.075*** *and* ***43.21C.080****. These rules attempt to construe and interpret the statutory provisions. In the event a court determines that these rules are inconsistent with statutory provisions, or with the framework and policy of SEPA, the statute will control. Persons considering either administrative or judicial appeal of any decision which involves SEPA at all are advised to read the statutory sections cited above.*

(2) ***Appeal to local legislative body.*** *RCW* ***43.21C.060*** *allows an appeal to a local legislative body of any decision by a local nonelected official conditioning or denying a proposal under authority of SEPA. Agencies may establish procedures for such an appeal, or may eliminate such appeals altogether, by rule, ordinance or resolution. Such appeals are subject to the restrictions in RCW* ***36.70B.050*** *and* ***36.70B.060*** *that local governments provide no more than one open record hearing and one closed record appeal for permit decisions.*

FOTC has appealed to the Sunnyside City Council three times under WAC 197-11-680(2). The first appeal was on September 22, 2023, likely beyond the short 20 day window prescribed in the Sunnyside Municipal Code section 2.72

(3) ***Agency administrative appeal procedures.***

(a) Agencies may provide for an administrative appeal of determinations relating to SEPA in their agency SEPA procedures. If so, the procedures must comply with the following:

(i) The agency must specify by rule, ordinance, or resolution that the appeals procedure is available.

(ii) Appeal of the intermediate steps under SEPA (e.g., lead agency determination, scoping, draft EIS adequacy) shall not be allowed.

(iii) Appeals on SEPA procedures shall be limited to review of a final threshold determination and final EIS. These appeals may occur prior to an agency's final decision on a proposed action.

The June 22, 2023 MDNS was a final threshold determination. Pacific Ag/Sunnyside RNG supplemented their environmental checklist with addenda on October 8, 2023. The City of Sunnyside posted a signed Notice of Addendum on November 28, 2023, with a deadline for comments of December 5, 2023.

Frankly, FOTC is confused regarding timelines for appeals, but we submit comments today to make sure we do not miss deadlines. This results in excess paperwork and excess documentation.

(iv) An agency shall provide for only one administrative appeal of a threshold determination or of the adequacy of an EIS; successive administrative appeals on these issues within the same agency are not allowed. This limitation does not apply to administrative appeals before another agency.

(v) Except as provided in (a)(vi) of this subsection, the appeal shall consolidate any allowed appeals of procedural and substantive determinations under SEPA with a hearing or appeal on the underlying governmental action in a single simultaneous hearing before one hearing officer or body. The hearing or appeal shall be one at which the hearing officer or body will consider either the agency's decision or a recommendation on the proposed underlying governmental action. For example, an appeal of the adequacy of an EIS must be consolidated with a hearing or appeal on the agency's decision or recommendation on the proposed action, if both proceedings are allowed in agency procedures. If an agency does not provide for a hearing or appeal on the underlying governmental action (either a hearing on the agency's recommendation or an agency appeal hearing after the decision is made), the agency may not hold a SEPA administrative appeal, except as allowed under (a)(vi) of this subsection.

This section says, *appeal shall consolidate any allowed appeals of procedural and substantive determinations under SEPA with a hearing or appeal on the underlying governmental action in a single simultaneous hearing before one hearing officer or body*. It does not say that appeals must be made to Superior Court as the City of Sunnyside advises.

(vi) The following appeals of SEPA procedural or substantive determinations need not be consolidated with a hearing or appeal on the underlying governmental action:

(A) An appeal of a determination of significance;

(B) An appeal of a procedural determination made by an agency when the agency is a project proponent, or is funding a project, and chooses to conduct its review under SEPA, including any appeals of its procedural determinations, prior to submitting an application for a project permit. Subsequent appeals of substantive determinations by an agency with jurisdiction over the proposed project shall be allowed under the SEPA appeal procedures of the agency with jurisdiction;

FOTC's July 6, 2023 appeal of the June 22, 2023 MDNS was mostly procedural. We believe that the City of Sunnyside and the Port of Sunnyside are project proponents based on the two years of meetings with Pacific Ag, the sale of property to Sunnyside RNG, and the extreme efforts the city and the port have exerted to move the SS RNG project forward. Based on WAC 197-11-680 (3)(a)(vi)(B) the City of Sunnyside should not have cancelled the August 23, 2023 appeal hearing.

(C) An appeal of a procedural determination made by an agency on a nonproject action; and

*(D) An appeal to the local legislative authority under RCW **43.21C.060** or other applicable state statutes.*

*(vii) If a county/city to which RCW **36.70B.110** applies provides for an administrative appeal, any such appeal of a procedural or substantive determination under SEPA issued at the same time as the decision on a project action shall be filed within fourteen days after a notice of decision under RCW **36.70B.130** or after other notice that the decision has been made and is appealable. In order to allow public comment on a DNS prior to requiring an administrative appeal to be filed, this appeal period shall be extended for an additional seven days if the appeal is of a DNS for which public comment is required under this chapter or under county/city rules adopted under SEPA. For threshold determinations issued prior to a decision on a project action, any administrative appeal allowed by a county/city shall be filed within fourteen days after notice that the determination has been made and is appealable. Nothing in this subsection alters the requirements of (a)(v) and (vi) of this subsection.*

(viii) Agencies shall provide that procedural determinations made by the responsible official shall be entitled to substantial weight.

*(b) Agencies providing for administrative appeals shall provide for a record as required by RCW **43.21C.075** (3)(c).*

(c) If an agency provides an administrative appeal procedure, that procedure must be used before anyone may initiate judicial review of any SEPA issue that could have been reviewed under the agency procedures.

The City of Sunnyside provides an administrative appeal procedure under Sunnyside Municipal Code Section 2.46 and 2.72. FOTC believes the City of Sunnyside erred by cancelling our August 23, 2023, appeal and telling us that our only option was to appeal permit decisions in Superior Court. WAC 197-11-680 (3)(c) says differently.

(4) Judicial appeals.

(a) SEPA authorizes judicial appeals of both procedural and substantive compliance with SEPA.

*(b) When SEPA applies to a decision, any judicial appeal of that decision potentially involves both those issues pertaining to SEPA (SEPA issues) and those which do not (non-SEPA issues). RCW **43.21C.075** establishes time limits for raising SEPA issues, but says that existing statutes of limitations control the appeal of non-SEPA issues. The statute contemplates a single lawsuit.*

(c) If there is a time limit established by statute or ordinance for appealing the underlying governmental action, then appeals (or portions thereof) raising SEPA issues must be filed within such time period.

The Sunnyside City Code states:

2.72.010 Appeal period.

Any appeal from any action of the City Council, City Commission or City Board, or City official or employee, whose decisions are not directly appealable to the City Council, must be brought within 20 days from the date of the effective date of the action appealed from. [Ord. 1313 § 1, 1981.]

The City of Sunnyside issued an MDNS for the SS RNG project. FOTC timely appealed. The city cancelled the appeal. After the threshold determination, SS RNG submitted changes to the environmental checklist that will affect the MDNS. FOTC may comment, but there is apparently no pathway for an appeal, according to the Sunnyside Municipal Code.

The City of Sunnyside may have designed a trap in which appeals were postponed and then prohibited due to postponement.

*(d) The notice of action procedures of RCW **43.21C.080** may still be used. If this procedure is used, then the time limits for judicial appeal specified in RCW **43.21C.080** shall apply, unless there is a time limit established by statute or ordinance for appealing the underlying governmental action. If so, the time limit for appeal of SEPA issues shall be the time limit in the statute or ordinance for the underlying governmental action. If the proposal requires more than one governmental decision that will be supported by the same SEPA documents, then RCW **43.21C.080** still only allows one judicial appeal of procedural compliance with SEPA, which must be commenced within the applicable time to appeal the first governmental decision.*

*(e) If the time limit established by statute or ordinance for appealing the underlying governmental action is less than fifteen days, then the notice of action in RCW **43.21C.080**(1) may be given by publishing once within that shorter time period, in a newspaper of general circulation in the area where the property that is the subject of the action is located, and meeting the other requirements of RCW **43.21C.080**.*

(f) If there is no time limit established by statute or ordinance for appeal, and the notice of action provisions are not used, then SEPA provides no time limit for judicial appeals. Appeal times may still be limited, however, by general statutes of limitation or the common law.

*(g) For the purposes of this subsection, "a time limit established by statute or ordinance" does not include time limits established by the general statutes of limitation in chapter **4.16** RCW.*

*(5) **Official notice of the date and place for commencing a judicial appeal.***

(a) Official notice of the date and place for commencing an appeal must be given if there is a time limit established by statute or ordinance for commencing an appeal of the underlying governmental action. The notice shall include:

(i) The time limit for commencing appeal of the underlying governmental action and SEPA issues, and the statute or ordinance establishing the time limit; and

(ii) Where an appeal may be filed.

(b) Notice is given by:

(i) Delivery of written notice to the applicant, all parties to any administrative appeal, and all persons who have requested notice of decisions with respect to the particular proposal in question; and

(ii) Following the agency's normal methods of notice for the type of governmental action taken.

(c) Written notice containing the information required by subsection (5)(a) of this section may be appended to the permit, decision documents, or SEPA compliance documents or may be printed separately.

(d) Official notices required by this subparagraph shall not be given prior to final agency action.

As noted above, FOTC is not certain of the intent of the City of Sunnyside's Notice of SEPA Addendum. FOTC could engage better if we knew whether these addenda would result in changes to the MDNS and consequently in final agency action.

The Notice of SEPA Addendum provides a window for public comments, but does not describe an appeal procedure. We understand that the lead agency has an obligation to evaluate and respond to our comments. See WAC 197-11-340 (2)(f)

WAC 197-11-910 Designation of responsible official.

*Agency SEPA procedures shall designate or provide a method of designating the responsible official with speed and certainty (WAC **197-11-906** (1)(d)). This designation may vary depending upon the nature of the proposal. The responsible official shall carry out the duties and functions of the agency when it is acting as the lead agency under these guidelines. Since it is possible under these rules for an agency to be acting as a lead agency prior to actually receiving an application for a license to undertake a private project, designation of the first department within the agency to receive an application as the responsible official will not be sufficient.*

It is FOTC's understanding that Trevor Martin from the City of Sunnyside is the responsible official for this SEPA determination.

WAC 197-11-924 Determining the lead agency.

*(1) The first agency receiving an application for or initiating a nonexempt proposal shall determine the lead agency for that proposal, unless the lead agency has been previously determined, or the agency receiving the proposal is aware that another agency is determining the lead agency. The lead agency shall be determined by using the criteria in WAC **197-11-926** through **197-11-944**.*

*(2) If an agency determines that another agency is the lead agency, it shall mail to such lead agency a copy of the application it received, together with its determination of lead agency and an explanation. If the agency receiving this determination agrees that it is the lead agency, it shall notify the other agencies with jurisdiction. If it does not agree, and the dispute cannot be resolved by agreement, the agencies shall immediately petition the department of ecology for a lead agency determination under WAC **197-11-946**.*

(3) Any agency receiving a lead agency determination to which it objects shall either resolve the dispute, withdraw its objection, or petition the department for a lead agency determination within fifteen days of receiving the determination.

*(4) An applicant may also petition the department to resolve the lead agency dispute under WAC **197-11-946**.*

*(5) To make the lead agency determination, an agency must determine to the best of its ability the range of proposed actions for the proposal (WAC **197-11-060**) and the other agencies with jurisdiction over some or all of the proposal. This can be done by:*

(a) Describing or requiring an applicant to describe the main features of the proposal;

(b) Reviewing the list of agencies with expertise;

(c) Contacting potential agencies with jurisdiction either orally or in writing.

It is FOTC's understanding that Pacific Ag/Sunnyside RNG may have approached Yakima County with this proposal prior to contacting the City and Port of Sunnyside.

WAC 197-11-92 Lead agency for governmental proposals.

(1) When an agency initiates a proposal, it is the lead agency for that proposal. If two or more agencies share in the implementation of a proposal, the agencies shall by agreement determine which agency will be the lead agency. For the purposes of this section, a proposal by an agency does not include proposals to license private activity.

(2) Whenever possible, agency people carrying out SEPA procedures should be different from agency people making the proposal.

WAC 197-11-928 Lead agency for public and private proposals.

*When the proposal involves both private and public activities, it shall be characterized as either a private or a public project for the purposes of lead agency designation, depending upon whether the primary sponsor or initiator of the project is an agency or from the private sector. Any project in which agency and private interests are too intertwined to make this characterization shall be considered a public project. The lead agency for all public projects shall be determined under WAC **197-11-926**.*

The City of Sunnyside's May 17, 2023 Notice of Environmental Review stated:

NOTICE OF ENVIRONMENTAL REVIEW This is to notify agencies with jurisdiction and environmental expertise and the public that the City of Sunnyside, Planning Division, has been established as the lead agency, under WAC § 197-11-928 for this project. The City of Sunnyside has reviewed the proposed project for probable adverse environmental impacts and expects to issue a Determination of Nonsignificance (DNS) per WAC § 197-11-355. The proposal may include mitigation measures under applicable codes and the project review process may incorporate or require mitigation measures regardless of whether an EIS is prepared. A copy of the subsequent threshold determination may be obtained by request and may be appealed pursuant to SMC Ch. 18.04.

Because this notice cited WAC 197-11-928, FOTC assumed this to be a public and private proposal. FOTC asked the City of Sunnyside several times whether it is a public and private project or a private project. The city did not answer. At a November 30, 2023 public meeting regarding the project, Harrison Pettit from Pacific Ag assured us several times that it is a private project. If this is so, then the City of Sunnyside was incorrect in

assuming the lead agency role, at least under WAC 197-11-928. FOTC asserts that the City of Sunnyside has an obligation to provide the public with accurate information.

WAC 197-11-930 Lead agency for private projects with one agency with jurisdiction.

For proposed private projects for which there is only one agency with jurisdiction, the lead agency shall be the agency with jurisdiction.

FOTC has asked the City of Sunnyside to list agencies with jurisdiction for the SS RNG project. The city has not answered.

* * * * * * * *

There are errors in the documents posted for this project:

- In the November 16, 2022, and May 17, 2023 Notice of Environmental Reviews the City of Sunnyside stated:

The City of Sunnyside has reviewed the proposed project for probable adverse environmental impacts and expects to issue a Determination of Nonsignificance (DNS) per WAC § 197-11-355.

But the City of Sunnyside has not incorporated WAC 197-11-355 by reference.

- In the November 16, 2022, and May 17, 2023 Notice of Environmental Reviews the City of Sunnyside stated:

This is to notify agencies with jurisdiction and environmental expertise and the public that the City of Sunnyside, Planning Division, has been established as the lead agency, under WAC § 197-11-928 for this project.

But WAC 197-11-928 refers to public and private projects. Sunnyside RNG claims this is a private project.

- Tax Parcel Numbers are listed as:

    - Notice of Environmental Review TAX PARCEL NUMBER(S): 220901-13001, -44401, -41404
    - Mitigated Determination of Non-Significance Parcel Number(s): 220901-13001, -44401, & -41404
    - Notice of Appeal Cancellation TAX PARCEL NUMBER(S): 220901-13001, -44401, -41404
    - Notice of SEPA Addendum TAX PARCEL NUMBER(S): 22090-141405 & 220901-41406 (Previously 220901-13001, -44401, - 41404)

- When did these changes occur? FOTC asks because we have spent many, many hours trying to make sense of the property location and zoning.

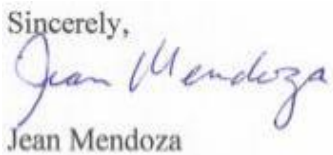
- Many related documents list two different File Numbers: SEPA-2022.0200 & SEPA 2023.0200 for the same project

- The October 8, 2023 Addendum Letter from Sunnyside RNG to the City of Sunnyside references File Number 2022.0200

- The October 8, 2023 Addendum Letter from Sunnyside RNG to the City of Sunnyside references Exhibit B, *A Cultural Resources Survey for the Sunnyside RNG project*. This document has not been posted for public view.

- The October 8, 2023 Addendum Letter from Sunnyside RNG to the City of Sunnyside also identifies Exhibit B as a *Traffic Impact Analysis*

- The signature date for this letter is November 8, 2023, while the heading date for the letter is October 8, 2023



- The November 28, 2023 Notice of SEPA Addendum says:

  There is a 14-day comment period for this review. This may be your only opportunity to comment. All written comments received by 5:00 p.m. on December 5, 2023. Please reference file numbers (SEPA-2022.0200) and applicant's name (Sunnyside RNG) in any correspondence you submit.

  We are not sure this is the correct File Number.

The Friends of Toppenish Creek appreciate this opportunity to comment on SEPA review for the SS RNG project. We request clarification on next steps, specifically the appeal process as interpreted by the Lead Agency, the City of Sunnyside.

Sincerely,

Jean Mendoza

Executive Director, Friends of Toppenish Creek
3142 Signal Peak Road
White Swan, WA 98952

Comments re Addendum to Sunnyside Renewable Natural Gas (SS RNG) SEPA document

Friends of Toppenish Creek is a 501 C (3) non profit group incorporated under the laws of Washington State and located in Yakima County. FOTC submits the following comments regarding an addendum submittal to a June 2023 SEPA review and mitigated determination of non-significance (MDNS) for a proposed Renewable Natural Gas (RNG) bio-digester at the Port of Sunnyside. The City of Sunnyside Notice of SEPA Addendum asked commenters to reference SEPA 2022.0200. We are not sure whether this is correct, or whether SEPA 2022.0200 exists.[1] The correct file number may be SEPA 2023.0200.

It is difficult to comment intelligently on this addendum submittal because the notice omits so much content. For example, the addendum includes a February 2023 New Source Review (NSR) application from Sunnyside RNG to the Yakima Regional Clean Air Agency (YRCAA) but omits the response from the YRCAA that rejected the application and requested more information.

FOTC believes that an MDNS should not have been issued until the City of Sunnyside and the public had the opportunity to review information on air emissions and traffic impacts. The MDNS was issued on June 22, 2023, but a Traffic Impact Analysis (TIA), that is part of the November 23, 2023 addendum letter, is dated July 10, 2023.

The Yakima Regional Clean Air Agency, as the agency with expertise on air, failed to comment on the May 2023 SEPA Review, as required by RCW 43.21C and WAC 197-11, and especially WAC 197-11-030, WAC 197-11-060(4), and WAC 197-11-502(2).

The City of Sunnyside did not have sufficient information to conclude no environmental impacts, and the public did not have sufficient information to comment intelligently on the May 2023 Environmental Review. The resulting MDNS is invalid due to withheld and/or insufficient information. See WAC 197-11-335, WAC 197-11-340(3), WAC 197-11-080.

* * * * * *

[1] FOTC does not find SEPA 2022.0200 in Ecology's State Environmental Policy Act (SEPA) Register at https://apps.ecology.wa.gov/separ/Main/SEPA/Search.aspx?SearchText=City%20of%20Sunnyside&SearchFields=All&County=YAKIMA&PageSize=10&SortColumn=LeadAgencyAscending&Page=17

According to a presentation by Pacific AG to the Port of Sunnyside[2] on September 6, 2022, the Sunnyside RNG facility could be "one of the largest ag waste anaerobic digesters in the nation."[3]

Realistically, how can "one of the largest waste anaerobic digesters in the nation" not have an impact on the environment?

The SS RNG project would:

- Produce between 800,000 & 950,000 MMBTUs of Renewable Natural Gas a year
- Produce and store methane, a flammable and explosive gas, in tanks with membrane covers
- Transfer the natural gas to a major pipeline
- Move 140 truckloads of manure every day from dairies to the digester
- Store digestate in stacks at the digester site and on farms
- Store liquid effluent from the digester in lagoons
- Spread digestate onto crop fields. There is insufficient information to determine the composition of the digestate and potential impacts on soil health and greenhouse gas emissions.

* * * * * * *

Manure bio-digesters are known to experience spills and explosions.[4] These adverse impacts are not expected to occur, but when they do occur the impacts are grave. Washington law accounts for this in WAC 197-11-794 (2).

FOTC has requested more information regarding fires and spills from Pacific AG, Sunnyside RNG, and Yakima County Emergency Services. The City of Sunnyside should not take further action on the SS RNG MDNS until this information arrives, and answers satisfy potentially impacted people.

* * * * * * *

FOTC believes the City of Sunnyside violated many sections of Washington SEPA law when the city issued the June 22, 2023 MDNS. These alleged violations are listed below. FOTC believes that the MDNS should be rescinded pursuant to WAC 197-11-340(3), a determination of non-significance (DNS) should be issued, and an Environmental Impact Statement (EIS) completed. Conducting a thorough EIS is the only way to adequately determine the environmental consequences of constructing such a large digester.

[2] See Attachment 1

[3] Harrison Pettit from Pacific Ag said this was not true at a public meeting in Sunnyside on November 30, 2023.

[4] See Attachment 2

WAC 197-11-030

Policy.

(1) The policies and goals set forth in SEPA are supplementary to existing agency authority.

(2) Agencies shall to the fullest extent possible:

(a) Interpret and administer the policies, regulations, and laws of the state of Washington in accordance with the policies set forth in SEPA and these rules.

(b) Find ways to make the SEPA process more useful to decision makers and the public; promote certainty regarding the requirements of the act; reduce paperwork and the accumulation of extraneous background data; and emphasize important environmental impacts and alternatives.

(c) Prepare environmental documents that are concise, clear, and to the point, and are supported by evidence that the necessary environmental analyses have been made.

(d) Initiate the SEPA process early in conjunction with other agency operations to avoid delay and duplication.

(e) Integrate the requirements of SEPA with existing agency planning and licensing procedures and practices, so that such procedures run concurrently rather than consecutively.

(f) Encourage public involvement in decisions that significantly affect environmental quality.

(g) Identify, evaluate, and require or implement, where required by the act and these rules, reasonable alternatives that would mitigate adverse effects of proposed actions on the environment.

The City of Sunnyside did not, to the fullest extent possible, *Interpret and administer the policies, regulations, and laws of the state of Washington in accordance with the policies set forth in SEPA and these rules.* Sunnyside did not compel the Yakima Regional Clean Air Agency to provide comments on air impacts from:

- Potential leaks at the digester site
- Transport of manure and digestate
- Leaks in pipes that transport natural gas
- 140 round trip truck trips per day
- Storage of manure and digestate in stacks and lagoons
- Spreading and spraying digestate on crop fields

The City of Sunnyside did not *promote certainty regarding the requirements of the act*. Sunnyside sent conflicting messages to the public by telling the public that an appeal was authorized, improperly stating the appeal would be a closed appeal, scheduling an appeal, and then canceling the appeal. Sunnyside did not respond to reasonable questions regarding the proposed RNG project.[5]

[5] See Attachment 3 FOTC Request for the City of Sunnyside to reconsider an MDNS for the Sunnyside RNG project. The City did not answer our questions.

The City of Sunnyside did not *emphasize important environmental impacts and alternatives.* Sunnyside did not explore or list alternatives to the project or citing of the project. Sunnyside did not describe potential air impacts or potential impacts to ground and/or surface waters at the Port of Sunnyside where monitoring wells have high levels of nitrate[6] and the Sulphur Creek Wasteway traverses the area. The City of Sunnyside did not address the potential for fires and explosions.

There were no analyses to prove statements by the project proponent, Pacific Ag/Sunnyside RNG, that the project would generate millions in tax dollars. There was no analysis of costs to tax payers in the form of subsidies, wear and tear on roadways, and decreased property values.

The City of Sunnyside did not *integrate the requirements of SEPA with existing agency planning and licensing procedures and practices, so that such procedures run concurrently rather than consecutively.* Instead Sunnyside issued an MDNS and then told FOTC that we could not appeal the MDNS until a later time after Pacific Ag applied for a permit.

The City of Sunnyside did not *encourage public involvement.* Instead, the city made it difficult for the public to be involved by not posting notices in newspapers, by not translating notices into Spanish, by only notifying about 20 neighbors of the SEPA review, by posting signs in a corn field, by not providing informational paperwork, by refusing to answer questions about the project, and by failure to attend a public meeting regarding the digester on November 30, 2023.

The City of Sunnyside did not *identify reasonable alternatives*, such as on-farm digesters, a more remote location, limitations on hours for manure transport, different methods of manure management and disposal, or the "no-action" alternative.

WAC 197-11-055
Timing of the SEPA Process

*(b) Agencies shall identify the times at which the environmental review shall be conducted either in their procedures or on a case-by-case basis. Agencies may also organize environmental review in phases, as specified in WAC **197-11-060**(5).*

---

[6] See Monitoring Wells LYV-PS-031, LYV-PS-032, and LYV-PS-033 on Ecology's Environmental Information Monitoring Data Base at https://apps.ecology.wa.gov/eim/search/Groundwater/GWSearchResults.aspx?ResultType=GroundwaterWellTab&StudyUserIds=MRED&StudyUserIdSearchType=Contains&LocationCounties=Yakima&HasGroundwaterData=True

The City of Sunnyside did not state that the environmental review for the Sunnyside RNG project would be organized in phases.

*(c) Appropriate consideration of environmental information shall be completed before an agency commits to a particular course of action (WAC **197-11-070**).*

The Port of Sunnyside committed to the Sunnyside RNG project by proposing the sale of property to Pacific AG in November 2022.[7] The City of Sunnyside issued a determination of non-significance for that sale on December 6, 2022.[8] Sale of real estate for a designated purpose is a commitment to a course of action.

Notice of the sale was not properly advertised. Public comments regarding the sale have not been posted. The City of Sunnyside approved an MDNS for the Sunnyside RNG project on June 22, 2023, six months after sale approval.

*(4) **Applicant review at conceptual stage.** In general, agencies should adopt procedures for environmental review and for preparation of EISs on private proposals at the conceptual stage rather than the final detailed design stage.*[9]

(a) If an agency's only action is a decision on a building permit or other license that requires detailed project plans and specifications, agencies shall provide applicants with the opportunity for environmental review under SEPA prior to requiring applicants to submit such detailed project plans and specifications.

*(b) Agencies may specify the amount of detail needed from applicants for such early environmental review, consistent with WAC **197-11-100** and **197-11-335**, in their SEPA or permit procedures.*

(c) This subsection does not preclude agencies or applicants from preliminary discussions or exploration of ideas and options prior to commencing formal environmental review.

On November 30, 2023, Harrison Pettit from Pacific AG told attendees at a public meeting regarding the Sunnyside RNG project that conversations regarding the project have been ongoing for two years. The fact that the Port of Sunnyside sold property to Pacific Ag for the project indicates a commitment on the part of the Port of Sunnyside and the City of Sunnyside to the biodigester project.

There is no documentation of alternatives as addressed in RCW 43.21C.030(2)(c)(iii), RCW 43.21C.030(2)(e), WAC 197-11-030(2), WAC 197-11-060 (1), WAC 197-11-060

---

[7] Port of Sunnyside Property Sale. http://www.friendsoftoppenishcreek.org/cabinet/data/AVS%203%20SS%20RNG%20Property%20Sale%20Notice.pdf

[8] DNS for Property Sale. http://www.friendsoftoppenishcreek.org/cabinet/data/SS%20RNG%20DNS_SEPA-2022.0046.pdf

[9] FOTC assumed in July of 2023 that the Sunnyside RNG project is a public and private partnership, based on statements in the June 22, 2023, MDNS. However, at a November 30, 2023 public meeting regarding the project, Harrison Pettit from Pacific Ag stated several times that this is a private project.

(2), WAC 197-11-060 (3), WAC 197-11-080(1), WAC 197-11-400 (2), WAC 197-11-402(1), WAC 197-11-402(9), WAC 197-11-408(2), WAC 197-11-440(4), WAC 197-11-440(5), WAC 197-11-655(3). According to WAC 197-11-440(5)(b)(ii) *The "no-action" alternative shall be evaluated and compared to other alternatives.*

*(5) An overall decision to proceed with a course of action may involve a series of actions or decisions by one or more agencies. If several agencies have jurisdiction over a proposal, they should coordinate their SEPA processes wherever possible. The agencies shall comply with lead agency determination requirements in WAC **197-11-050** and **197-11-922**.*

(6) To meet the requirement to insure that environmental values and amenities are given appropriate consideration along with economic and technical considerations, environmental documents and analyses shall be circulated and reviewed with other planning documents to the fullest extent possible.

Selected environmental documents for the Sunnyside RNG project were first shared with the public on May 23, 2023. A Traffic Impact Analysis was not published until July of 2023. There is still no approved air study. Questions regarding increased pollution related to the production of manure to feed the digester, and emissions from the digestate produced by the digester have not been answered.

WAC 197-11-060 (4) Impacts.

*(a) SEPA's procedural provisions require the consideration of "environmental" impacts (see definition of "environment" in WAC **197-11-740** and of "impacts" in WAC **197-11-752**), with attention to impacts that are likely, not merely speculative. (See definition of "probable" in WAC **197-11-782** and **197-11-080** on incomplete or unavailable information.)*

*(b) In assessing the significance of an impact, a lead agency shall not limit its consideration of a proposal's impacts only to those aspects within its jurisdiction, including local or state boundaries (see WAC **197-11-330**(3) also).*

(c) Agencies shall carefully consider the range of probable impacts, including short-term and long-term effects. Impacts shall include those that are likely to arise or exist over the lifetime of a proposal or, depending on the particular proposal, longer.

(d) A proposal's effects include direct and indirect impacts caused by a proposal. Impacts include those effects resulting from growth caused by a proposal, as well as the likelihood that the present proposal will serve as a precedent for future actions. For example, adoption of a zoning ordinance will encourage or tend to cause particular types of projects or extension of sewer lines would tend to encourage development in previously unsewered areas.

*(e) The range of impacts to be analyzed in an EIS (direct, indirect, and cumulative impacts, WAC **197-11-792**) may be wider than the impacts for which mitigation measures are required of applicants (WAC **197-11-660**). This will depend upon the specific impacts, the extent to which the adverse impacts are attributable to the applicant's proposal, and the capability of applicants or agencies to control the impacts in each situation.*

This is a large project. This bio-digester may be one of the largest in the United States. Impacts will extend beyond the Sunnyside City Limits.

- There will be increased traffic on Yakima County roads to haul manure and crop residues to the digester, to haul digestate from the digester, to haul composted digestate to markets. Increased traffic brings increased pollution of the air with nitrogen oxides and particulate matter. Increased traffic brings increased wear and tear on county roads and costs to tax payers across the county. FOTC submitted an evaluation of the Sunnyside RNG TIA to Yakima County and the Port of Sunnyside on August 28, 2023.[10] We await responses.
- If dairies receive up to $200 per year per cow for manure, there is an incentive to increase the number of cows in each herd. More cows mean increased leaching to the aquifers, and increased air emissions. More cows mean more land taken out of production of fruits and vegetables and more land devoted to dairies and cattle feed. Corn and alfalfa, the major crops for cattle feed, require large amounts of water. Corn is hard on the land, requires large amounts of fertilizer and introduces a wide range of plant pathogens.
- FOTC does not believe it is possible to test for and screen out all the possible contaminants in digestate. There is a significant risk of spreading pathogens to a large number of farming operations when digestate is spread as fertilizer or used as animal bedding. For example, cryptosporidium is a common and wide spread zoonotic parasite that attacks young calves and is more common on dairies with intense confinement and moist conditions.[11] If there is cryptosporidium in manure used as feedstock, the parasite may proliferate in the digesters, live in the digestate, and infect soils for miles around where farmers spread digestate. Cryptosporidium could infect large numbers of animals housed in facilities that use the digestate for bedding.
- If dairies receive up to $200 per year per cow for manure, the up to 25 LYV dairies that participate in this project have a serious economic advantage over the 15 or more dairies that do not. If a dairy has 1,000 milk cows and receives $200 per year per cow, that dairy will increase annual income by $200,000. This makes a difference in which dairies survive and which do not.
- Sunnyside RNG has not described contracts with dairies. FOTC believes there is a potential for this project to squeeze out non-participating dairies and to create dairy dependence on the digester for economic survival. If dependence occurs, then LYV dairies are at the mercy of digester operators who can raise or lower the rates of payment for manure. There is a troubled dairy digester in Iowa where

[10] See Attachment 4

[11] Oregon State University. The cryptosporidium parasite and its effect on calves and humans. https://extension.oregonstate.edu/animals-livestock/beef/cryptosporidium-parasite-its-effect-calves-humans *Cryptosporidium is* most infectious when the parasite is passed in feces and then ingested. Infected calves can have crypto in their feces for weeks after they are no longer sick.
Crypto eggs have a tough outer shell and are resistant to disinfectants, even chlorine bleach. They can survive outside the body and in the environment for long periods. The eggs can be killed by generous applications of a 3% hydrogen peroxide solution as well as exposure to high temperatures in excess of 160° F, which is hotter than most domestic tap water.

economic benefits do not pencil out. A recent newspaper article[12] about the Waunakee Digester in Wisconsin stated:

Many of the assumptions the company made at the start were wrong. In the future, the business model will have to be tweaked, and farmers sending manure to comparable operations may need to pay the plant to accept it.

- Regarding global warming: To our knowledge no one has calculated how much diesel fuel would be burned to transport manure and digestate for this project.
- Regarding global warming: Dairies produce at least one metric ton of CO_2 equivalents via enteric fermentation for every metric ton of methane produced in anaerobic manure lagoons. Consider a hypothetical community that produces 0.5 MMT CO_2 equivalents of methane via enteric fermentation, and 0.5 MMT CO_2 equivalents of methane from manure lagoons. This equals 1 MMT CO_2 equivalents of methane total. Suppose the community can process all the methane from manure lagoons into renewable natural gas. The total is now 0.5 MMT CO_2 equivalents of methane. Because the operation is profitable the community doubles the number of cows. All the methane from manure lagoons is captured, but the community now produces 1 MMT CO_2 equivalents of methane from enteric fermentation – back to the starting point. Plus the emission of other air pollutants has doubled & emissions from manure transport has doubled, etc.
- We do not see an accounting of how much income for the proposed digester comes from the Washington Cap and Trade program, and from tax payers. The Cap and Trade program does not last forever. Can the Sunnyside RNG digester continue to profit if subsidies decline?
- According to the EPA AgStar program[13] there are many ways to reduce methane emissions from livestock manure management. Some methods are:
    - *Anaerobic digesters – 50% reduction*
    - *Daily spread – 45% reduction*
    - *Pasture based management – 45% reduction*
    - *Composting – 45% reduction*
    - *Solid storage – 45% reduction*
    - *Manure drying practices – 45% reduction*
    - *Semi-permeable covers – 40% reduction*
    - *Decreased manure storage time – 40% reduction*
    - *Composted bedded pack barns – 30% reduction*
    - *Solid separation of manure solids prior to entry to wet/anaerobic environment – 20% reduction*

  But anaerobic digesters cost so much more than the other methods.

[12] State-financed manure digester plagued by spills, explosions. 2015. https://archive.jsonline.com/news/statepolitics/state-financed-manure-digester-plagued-by-spills-explosion-b99435123z1-290263421.html

[13] EPA AgStar. (2023) Practices to Reduce Methane Emissions from Livestock Manure Management. https://www.epa.gov/agstar/practices-reduce-methane-emissions-livestock-manure-management

- The Sunnyside RNG New Source Review (NSR) application requires more information and does not quantify the amount of air pollutants currently in the LYV ambient air. It does not estimate the percentage of air pollution attributable to the proposed Sunnyside RNG digester if it becomes reality. Would Sunnyside residents be forced to stop using wood stoves to compensate for digester emissions to keep Yakima County in compliance with U.S. criteria air standards?
- There are significant increases in morbidity and mortality associated with fine particulate air pollution.[14] One study found a decrease of 10 $\mu g/m^3$ of fine particulate concentration was associated with an estimated increase in life expectancy equal to 0.77 years.[15] By how much would fine particulate matter levels increase in the LYV if the Sunnyside RNG digester were built? What is the cost of human health and life?

WAC 197-11-060 Content of Environmental Review

(5) ***Phased review.***

(a) Lead agencies shall determine the appropriate scope and level of detail of environmental review to coincide with meaningful points in their planning and decision-making processes. (See WAC ***197-11-055*** *on timing of environmental review.)*

(b) Environmental review may be phased. If used, phased review assists agencies and the public to focus on issues that are ready for decision and exclude from consideration issues already decided or not yet ready. Broader environmental documents may be followed by narrower documents, for example, that incorporate prior general

Relationships between fine particulate air pollution, cardiometabolic disorders, and cardiovascular mortality. *Circulation research*, *116*(1), 108-115. https://www.ahajournals.org/doi/full/10.1161/circresaha.116.305060

[15] Pope CA 3rd, Ezzati M, Dockery DW. Fine-particulate air pollution and life expectancy in the United States. N Engl J Med. 2009 Jan 22;360(4):376-86. doi: 10.1056/NEJMsa0805646. PMID: 19164188; PMCID: PMC3382057. https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3382057/

discussion by reference and concentrate solely on the issues specific to that phase of the proposal.

(c) Phased review is appropriate when:

*(i) The sequence is from a nonproject document to a document of narrower scope such as a site specific analysis (see, for example, WAC **197-11-443**); or*

(ii) The sequence is from an environmental document on a specific proposal at an early stage (such as need and site selection) to a subsequent environmental document at a later stage (such as sensitive design impacts).

(d) Phased review is not appropriate when:

(i) The sequence is from a narrow project document to a broad policy document;

(ii) It would merely divide a larger system into exempted fragments or avoid discussion of cumulative impacts; or

*(iii) It would segment and avoid present consideration of proposals and their impacts that are required to be evaluated in a single environmental document under WAC 197-11-060 (3)(b) or **197-11-305**(1); however, the level of detail and type of environmental review may vary with the nature and timing of proposals and their component parts.*

(e) When a lead agency knows it is using phased review, it shall so state in its environmental document.

(f) Agencies shall use the environmental checklist, scoping process, nonproject EISs, incorporation by reference, adoption, and supplemental EISs, and addenda, as appropriate, to avoid duplication and excess paperwork.

*(g) Where proposals are related to a large existing or planned network, such as highways, streets, pipelines, or utility lines or systems, the lead agency may analyze in detail the overall network as the present proposal or may select some of the future elements for present detailed consideration. Any phased review shall be logical in relation to the design of the overall system or network, and shall be consistent with this section and WAC **197-11-070**.*

The City of Sunnyside did not state that the city would use a phased review. FOTC believes the City of Sunnyside should have gathered information sooner and presented all relevant environmental information with the initial SEPA review. Because the process now involves addressing a SEPA Review and then addressing Addenda to the SEPA review, the amount of study and paperwork has doubled, at least for FOTC.

WAC 197-11-080

Incomplete or unavailable information.

(1) If information on significant adverse impacts essential to a reasoned choice among alternatives is not known, and the costs of obtaining it are not exorbitant, agencies shall obtain and include the information in their environmental documents.

(2) When there are gaps in relevant information or scientific uncertainty concerning significant impacts, agencies shall make clear that such information is lacking or that substantial uncertainty exists.

(3) Agencies may proceed in the absence of vital information as follows:

(a) If information relevant to adverse impacts is essential to a reasoned choice among alternatives, but is not known, and the costs of obtaining it are exorbitant; or

(b) If information relevant to adverse impacts is important to the decision and the means to obtain it are speculative or not known;

Then the agency shall weigh the need for the action with the severity of possible adverse impacts which would occur if the agency were to decide to proceed in the face of uncertainty. If the agency proceeds, it shall generally indicate in the appropriate environmental documents its worst case analysis and the likelihood of occurrence, to the extent this information can reasonably be developed.

*(4) Agencies may rely upon applicants to provide information as allowed in WAC **197-11-100**.*

The City of Sunnyside did not document incomplete information, as required in the rule. FOTC believes that significant information is missing, and this should have been documented. See the concerns described on pages 6 to 9 above. We are especially concerned about costs to tax payers, impact on non-participating dairies and other farms, spreading disease, unknown increases in LYV air pollution, wear and tear on county roads, increases in traffic accidents, dangers to school children, and risks of fire and explosions.

Although the chances of fires and explosions are not great, damage when such incidents occur may be high and could include death.[16] A quality SEPA review must acknowledge this risk and address it. See WAC 197-11-794 (2).

The Sunnyside RNG SEPA Check list says:

Anaerobic-digestor-based renewable natural gas facilities produce biogas composed of methane (CH4) which is a flammable gas (under limited circumstances), hydrogen sulfide (H2S) which is both a flammable and toxic gas, along with CO2 and vocs. These components will be contained in anaerobic tanks with membrane roofs and in the downstream raw biogas piping systems designed in compliance with industry standards for sour gas facilities.

Methane (CH4) and Hydrogen Sulfide (H2S) are products of the anaerobic digestion process and both are considered hazardous with H2S also considered toxic. Both components will be present in the facility tanks and piping. Their hazardous and/or toxic characteristics along with response measures, should either be released to the atmosphere, can be found in Safety Data Sheets (SDS). Process chemicals such as solvents, oils, lubricants, antifreeze, ferric chloride and natural gas injection calibration gases such as Nitrogen, Propane, Helium, and potentially odorant will be used in limited quantities.

Standard emergency and fire services, as well as potentially confined space rescue. Other special health and safety planning is underway and will be confirmed with emergency

[16] See Attachment 2

services and County Health Department. Standard emergency services equipment includes self-contained breathing apparatus (SCBA) appropriate for potential exposure.

The following measures may be implemented to reduce or control environmental health hazards: A health and safety plan would be followed during construction to address worker safety and to minimize exposure to potential environmental health hazards. To help detect potential leaks quickly, an odorant may be added to the gas . Pressure and flow at the facilities will be monitored to ensure proper operation and reduce potential risk for fire and explosion. The centralized gas cleaning unit would be designed with internal shutoff valves that will switch automatically if the system detects a malfunction. The centralized gas cleaning unit would be outfitted with control technology to ensure that emissions are below the acceptable source impact level for air pollutants associated with project operation. The extremely limited areas where toxic/ hazardous materials are utilized will have impermeable surfaces and curbing to contain any potential spills.

Every methane producing facility with spills, leaks, fires, and explosions said the same things when they convinced communities to permit operations. Nothing in this statement is enforceable.[17]

The checklist says, *The following measures <u>may be implemented</u> to reduce or control environmental health hazards.*

If there is an accident and victims argue for compensation, Sunnyside RNG insurance companies can simply say, 'W never promised to do those things. We said those measures *may be implemented*.'

A useful SEPA check list would tell the reader, among other things:

- Where on the facility would alarms and monitors be located?
- What would be the pressure and flow danger signs?
- Would monitoring be automated or by trained personnel?
- What would the alarms detect?
- Frequency of alarm checks to make sure they function properly?
- How would the facility check for corrosion in the piping system, in the tank floors and walls?
- How often would piping be checked for leaks?
- When would equipment be replaced as the facility ages?
- Required safety training for staff – content, how often?
- Evacuation routes?
- What are protocols for rescuing trapped and endangered workers?
- Would there be monitoring for release of pathogens in effluent and air?
- Would there be fenceline monitoring?

[17] The City of Sunnyside Municipal Code 18.04.120.E.3 states: *The applicant's proposed mitigation measures must be in writing and must be specific. For example, proposals to "control noise" or "prevent storm water runoff" are inadequate, whereas proposals to "muffle machinery to X decibels" or "construction 200-foot storm water retention pond at Y location" are adequate.*

- What are proposed protocols for notifying neighbors of leaks and dangers?
- Describe a worst case scenario for fires and explosions

WAC 197-11-158 SEPA/GMA project review—Reliance on existing plans, laws, and regulations.

*(1) In reviewing the environmental impacts of a project and making a threshold determination, a GMA county/city may, at its option, determine that the requirements for environmental analysis, protection, and mitigation measures in the GMA county/city's development regulations and comprehensive plan adopted under chapter **36.70A** RCW, and in other applicable local, state, or federal laws or rules, provide adequate analysis of and mitigation for some or all of the specific adverse environmental impacts of the project.*

(2) In making the determination under subsection (1) of this section, the GMA county/city shall:

*(d) Place the following statement in the threshold determination if all of a project's impacts are addressed by other applicable laws and no conditions will be required under SEPA: "The lead agency has determined that the requirements for environmental analysis, protection, and mitigation measures have been adequately addressed in the development regulations and comprehensive plan adopted under chapter **36.70A** RCW, and in other applicable local, state, or federal laws or rules, as provided by RCW **43.21C.240** and WAC 197-11-158. Our agency will not require any additional mitigation measures under SEPA."*

The City of Sunnyside did not select this option.

WAC 197-11-164 Planned actions—Definition and criteria.

*(1) Under RCW **43.21C.440**, GMA counties/cities may designate a planned action.*

FOTC interpretation is that the Sunnyside RNG project is not a planned action.

WAC 197-11-330 Threshold determination process.

*(3) In determining an impact's significance (WAC **197-11-794**), the responsible official shall take into account the following, that:*

(a) The same proposal may have a significant adverse impact in one location but not in another location;

(b) The absolute quantitative effects of a proposal are also important, and may result in a significant adverse impact regardless of the nature of the existing environment;

(c) Several marginal impacts when considered together may result in a significant adverse impact;

(d) For some proposals, it may be impossible to forecast the environmental impacts with precision, often because some variables cannot be predicted or values cannot be quantified.

(e) A proposal may to a significant degree:

(i) Adversely affect environmentally sensitive or special areas, such as loss or destruction of historic, scientific, and cultural resources, parks, prime farmlands, wetlands, wild and scenic rivers, or wilderness;

(ii) Adversely affect endangered or threatened species or their habitat;

(iii) Conflict with local, state, or federal laws or requirements for the protection of the environment; and

(iv) Establish a precedent for future actions with significant effects, involves unique and unknown risks to the environment, or may affect public health or safety.

*(4) If after following WAC **197-11-080** and **197-11-335** the lead agency reasonably believes that a proposal may have a significant adverse impact, an EIS is required.*

(5) A threshold determination shall not balance whether the beneficial aspects of a proposal outweigh its adverse impacts, but rather, shall consider whether a proposal has any probable significant adverse environmental impacts under the rules stated in this section. For example, proposals designed to improve the environment, such as sewage treatment plants or pollution control requirements, may also have significant adverse environmental impacts.

Many people believe that the SS RNG digester should be located away from the City of Sunnyside, in a more remote area.

People note that the proposed digester will be situated near the Windmill Mushroom Farms that already sends odorous emissions into the ambient air, and the Nutrien Fertilizer Plant with a history of a fire that required evacuation of neighbors, and the Sunnyside wastewater treatment plant that sprays odorous effluent onto nearby fields.

The proposed digester would be near the area where the poorer people of Sunnyside live and farther from more affluent areas. A previous site, near more affluent areas, and near the Williams natural gas pipeline, was rejected. No one is stating the reason.

Soil at this site, Quincy loamy fine sand, is “excessively drained” according to the Natural Resources Conservation Service. Nearby monitoring wells at the Port of Sunnyside show high levels of nitrates in the underlying aquifer. Sunnyside RNG has not stated what kind of liner will be used for digester lagoons. It is reasonable to expect that spills on the digester site would quickly leach to the aquifer.

Approval of this project without an Environmental Impact Statement would demonstrate to the public that Washington laws to protect people in marginalized neighborhoods mean nothing.

197-11-335 Additional information.

*The lead agency shall make its threshold determination based upon information reasonably sufficient to evaluate the environmental impact of a proposal (WAC **197-11-055**(2) and **197-11-060**(3)). The lead agency may take one or more of the following actions if, after reviewing the checklist, the agency concludes that there is insufficient information to make its threshold determination:*

(1) Require an applicant to submit more information on subjects in the checklist;

(2) Make its own further study, including physical investigations on a proposed site;

*(3) Consult with other agencies, requesting information on the proposal's potential impacts which lie within the other agencies' jurisdiction or expertise (agencies shall respond in accordance with WAC **197-11-550**); or*

*(4) Decide that all or part of the action or its impacts are not sufficiently definite to allow environmental analysis and commit to timely, subsequent environmental analysis, consistent with WAC **197-11-055** through **197-11-070**.*

There is insufficient information in the Sunnyside RNG checklist to evaluate the environmental impact of the proposed digester.

- Only vague speculation about project expansion
- A Geotechnical Report and Phase I ESA are referenced but not available for review
- There is no air permit. The application posted on the City of Sunnyside web site that appears to have been accepted by the Yakima Regional Clean Air Agency was not in fact accepted. The YRCAA returned it to Sunnyside RNG for more information
- Could the answers be any vaguer? How about this: "Best management practices will be used to reduce and control erosion. Local and state laws will be followed. Silt fence, construction entrance, an inlet protection are planned."[18]
- The Environmental Checklist assures the public that emissions from the proposed digester will not exceed:
    - CO - 100 tons per year (tpy)
    - NOX - 40 tons per year (tpy)
    - SO2 - 40 tons per year (tpy)
    - PM - 25 tons per year (tpy)
    - PM10-15tpy
    - PM25 -10 tpy

[18] The City of Sunnyside Municipal Code 18.04.120.E.3 states: *The applicant's proposed mitigation measures must be in writing and must be specific. For example, proposals to "control noise" or "prevent storm water runoff" are inadequate, whereas proposals to "muffle machinery to X decibels" or "construction 200-foot storm water retention pond at Y location" are adequate.*

Suppose the SS RNG digester only emits 5 tons per year of PM 2.5, fine particulate matter, and Windmill Mushroom Farms only emits 5 tons per year of fine particulate matter, and Nutrien Solutions only emits 5 tons per year of fine particulate matter, and the City of Sunnyside Waste Water Treatment Plant only emits 5 tons per year of fine particulate matter. The Total is 20 tons per year. What does this mean for South Sunnyside air quality? Wouldn't it be better to study this problem before ground is broken, rather than trying to protect human health with home air filters and breathing treatments afterwards?

- *Stormwater runoff will be retained on site and infiltrated into the ground at various locations including a potential stormwater pond. This water will not flow into other waters.* This means that stormwater will wash spilled manure and digestate from the site into the ground. Who will monitor for onsite spills? Is groundwater monitoring appropriate here?
- *Natural gas used for heat (the boilers) is accounted for in the air emissions as well as avoided methane calculations.* This natural gas should not be counted in avoided methane calculations.
- *Thermal energy will be recaptured from the amine re boiler for heating other site processes. Where appropriate variable rate pumps will be used.* There is insufficient information to quantify these proposed savings. There is insufficient information for the average reader, including City of Sunnyside Officials, to understand the nature of an amine boiler.
- *To help detect potential leaks quickly, an odorant may be added to the gas*. An odorant "may" be added. You "may" win the lottery
- *Noise is not anticipated to be a problem*. Please tell us why not.
- FOTC's table top calculation, using data from the SS RNG Traffic Impact Analysis estimates there will be an additional 1,500 miles of truck traffic per day mostly on Yakima County Roads. Heavy duty trucks inflict about 2,500 times more wear and tear on roads than private cars. There is no estimate of cost to maintain the impacted county roads.

WAC 197-11-340 Determination of nonsignificance (DNS).

(2)(c) Any person, affected tribe, or agency may submit comments to the lead agency within fourteen days of the date of issuance of the DNS.
(2)(f) The responsible official shall reconsider the DNS based on timely comments and may retain or modify the DNS or, if the responsible official determines that significant adverse impacts are likely, withdraw the DNS or supporting documents. When a DNS is modified, the lead agency shall send the modified DNS to agencies with jurisdiction.
(3)(a) The lead agency shall withdraw a DNS if:

(i) There are substantial changes to a proposal so that the proposal is likely to have significant adverse environmental impacts;

(ii) There is significant new information indicating, or on, a proposal's probable significant adverse environmental impacts; or

(iii) The DNS was procured by misrepresentation or lack of material disclosure; if such DNS resulted from the actions of an applicant, any subsequent environmental

checklist on the proposal shall be prepared directly by the lead agency or its consultant at the expense of the applicant.

(b) Subsection (3)(a)(ii) shall not apply when a nonexempt license has been issued on a private project.

*(c) If the lead agency withdraws a DNS, the agency shall make a new threshold determination and notify other agencies with jurisdiction of the withdrawal and new threshold determination. If a DS is issued, each agency with jurisdiction shall commence action to suspend, modify, or revoke any approvals until the necessary environmental review has occurred (see also WAC **197-11-070**).*

The City of Sunnyside issued a mitigated determination of non-significance (MDNS) of the SS RNG project on June 22, 2023.

The Friends of Toppenish Creek submitted an appeal of the MDNS on July 6, 2023.[19]

There is no evidence that the responsible official reconsidered the MDNS based on FOTC's lengthy comments, as required by WAC 197-11-340(2)(f).

FOTC maintains there was a lack of material disclosure due to the absence of data regarding air quality, risks for fires and explosion, and traffic impacts. The agency with expertise for air, the YRCAA, did not comment. A Traffic Impact Analysis (TIA) was not available for review prior to our July 6, 2023 appeal.

WAC 197-11-350 Mitigated DNS.

The purpose of this section is to allow clarifications or changes to a proposal prior to making the threshold determination.

(1) In making threshold determinations, an agency may consider mitigation measures that the agency or applicant will implement.

(2) After submission of an environmental checklist and prior to the lead agency's threshold determination on a proposal, an applicant may ask the lead agency to indicate whether it is considering a DS. If the lead agency indicates a DS is likely, the applicant may clarify or change features of the proposal to mitigate the impacts which led the agency to consider a DS likely. The applicant shall revise the environmental checklist as may be necessary to describe the clarifications or changes. The lead agency shall make its threshold determination based upon the changed or clarified proposal. If a proposal continues to have a probable significant adverse environmental impact, even with mitigation measures, an EIS shall be prepared.

(3) Whether or not an applicant requests early notice under subsection (2), if the lead agency specifies mitigation measures on an applicant's proposal that would allow it to issue a DNS, and the proposal is clarified, changed, or conditioned to include those measures, the lead agency shall issue a DNS.

[19] See Attachment 2

(4) Environmental documents need not be revised and resubmitted if the clarifications or changes are stated in writing in documents that are attachments to, or incorporate by reference, the documents previously submitted. An addendum may be used, see Part Six.

The June 22, 2023 MDNS for the SS RNG project stated the following mitigation measures:

Mitigation Measure: An Inadvertent Discovery Plan shall be created and submitted to the City of Sunnyside as part of the building permit package for the prosed development.

Mitigating Measures: a stormwater management plan is required to be submitted for review and approval by City of Sunnyside public works department prior to construction. The plan must meet the following design standards:

a) Stormwater retention or detention shall be provided. A professional engineer registered in the state of Washington shall design all drainage facilities and components. Drainage plans using best management practices and design requirements must be submitted to and approved by City of Sunnyside prior to grading or development.
b) Post development stormwater flow rates and volumes shall not exceed predevelopment conditions. The standard of full retention of the 25-year storm event generally meets the goal.
c) The depth to groundwater should be determined prior to planning the layout of stormwater facilities. If a stormwater infiltration facility will be used for the disposal of runoff, a permeability test should be conducted initially at the site to determine existing infiltration rates prior to the design stage.

Mitigation Measure: Dust a. A dust control plan must be filed with the Yakima Regional Clean Air Authority.

Documentation for most of these mitigation measures is still missing, namely there is no:

- Inadvertent Discovery Plan, although the addendum letter from SS RNG claims one exists
- NPDES Construction Stormwater permit, although the addendum letter from SS RNG claims one exists
- Stormwater Pollution Prevention Plan, although the addendum letter from SS RNG claims one exists
- Consultation with the WA State Dept. of Ecology and the Yakima Health District regarding a Notice of Intent to operate under terms and conditions of a solid waste permit
- Depth to groundwater and permeability tests

On December 4, 2023, FOTC submitted a public records request to Yakima County Emergency Services for information re conversations with Sunnyside RNG regarding possible fires and explosions. On December 5, 2023, Yakima County Emergency

Services informed FOTC that they have no records of conversations with Pacific Ag/Sunnyside RNG regarding the proposed manure bio-digester.

FOTC interprets this to mean that project proponents have not adequately prepared for possible fires and explosions at the site. There is abundant information demonstrating the possibility of fires and explosions related to methane production facilities.

WAC 197-11-355 Optional DNS process.

In the City of Sunnyside's May 23, 2023 Notice of Environmental Review the city stated:

NOTICE OF ENVIRONMENTAL REVIEW This is to notify agencies with jurisdiction and environmental expertise and the public that the City of Sunnyside, Planning Division, has been established as the lead agency, under WAC § 197-11-928 for this project. The City of Sunnyside has reviewed the proposed project for probable adverse environmental impacts and expects to issue a Determination of Nonsignificance (DNS) per WAC § 197-11-355. The proposal may include mitigation measures under applicable codes and the project review process may incorporate or require mitigation measures regardless of whether an EIS is prepared. A copy of the subsequent threshold determination may be obtained by request and may be appealed pursuant to SMC Ch. 18.04.

However the City of Sunnyside has not incorporated WAC 197-11-355 by reference. See City of Sunnyside Municipal Code, Chapter 18.04 available at https://www.codepublishing.com/WA/Sunnyside/#!/Sunnyside18/Sunnyside1804.html#18.04.020

18.04.080 Categorical exemptions and threshold determinations, provisions adopted by reference.

Regarding the rules for deciding whether a proposal has a "probable significant adverse environmental impact" requiring an EIS to be prepared, and the rules for evaluating the impacts of proposals not requiring an EIS, the City adopts the following sections of Chapter 197-11 WAC by reference:

WAC

197-11-300 Purpose
197-11-305 Categorical Exemptions
197-11-310 Threshold Determination Required
197-11-315 Environmental Checklist
197-11-330 Threshold Determination Process
197-11-335 Additional Information
197-11-340 Determination of Non-Significance

197-11-350 Mitigated Determinations of Non-Significance

197-11-360 Determinations of Significance/Initiation of Scoping

197-11-390 Effects of Threshold Determination

[Ord. 1475 § 2, 1984.]

FOTC questions whether the city can invoke a rule that the city has not approved. The city did not respond when FOTC brought this fact to the city's attention.

WAC 197-11-400 Purpose of EIS.

(1) The primary purpose of an environmental impact statement is to ensure that SEPA's policies are an integral part of the ongoing programs and actions of state and local government.

(2) An EIS shall provide impartial discussion of significant environmental impacts and shall inform decision makers and the public of reasonable alternatives, including mitigation measures, that would avoid or minimize adverse impacts or enhance environmental quality.

(3) Environmental impact statements shall be concise, clear, and to the point, and shall be supported by the necessary environmental analysis. The purpose of an EIS is best served by short documents containing summaries of, or reference to, technical data and by avoiding excessively detailed and overly technical information. The volume of an EIS does not bear on its adequacy. Larger documents may even hinder the decision making process.

(4) The EIS process enables government agencies and interested citizens to review and comment on proposed government actions, including government approval of private projects and their environmental effects. This process is intended to assist the agencies and applicants to improve their plans and decisions, and to encourage the resolution of potential concerns or problems prior to issuing a final statement. An environmental impact statement is more than a disclosure document. It shall be used by agency officials in conjunction with other relevant materials and considerations to plan actions and make decisions.

An Environmental Impact Statement, as described in WAC 197-11-400 is essential for quality decision making. A project as large as the Sunnyside RNG digester should not proceed without study of environmental information at this level

WAC 197-11-500 Purpose of this part.

This part provides rules for:

(1) Notice and public availability of environmental documents, especially environmental impact statements;

(2) Consultation and comment by agencies and members of the public on environmental documents;

(3) Public hearings and meetings; and

(4) Lead agency response to comments and preparation of final environmental impact statements. Review, comment, and responsiveness to comments on a draft EIS are the focal point of the act's commenting process because the DEIS is developed as a result of scoping and serves as the basis for the final statement.

This section especially addresses public notice for Environmental Impact Statements, but it is not limited to EIS. FOTC believes that this section also addresses Environmental Review in sections that do not limit discussion to EIS.

WAC 197-11-502 Inviting comment.

(1) Agency efforts to involve other agencies and the public in the SEPA process should be commensurate with the type and scope of the environmental document.

*(2) Consulted agencies have a responsibility to respond in a timely and specific manner to requests for comments (WAC **197-11-545**, **197-11-550**, and **197-11-724**).*

The Yakima Regional Clean Air Agency, the agency tasked with enforcing the Clean Air Act in Yakima County, did not respond to the City of Sunnyside's request for comments on the May 2023 Notice of Environmental Review. Consequently the MDNS did not contain sufficient analysis of related air impacts. If there were an adequate analysis of air impacts the City of Sunnyside might have issued a Determination of Significance that would have changed the course of these actions.

*(3) **Threshold determinations.***

*(a) Agencies shall send DNSs to other agencies with jurisdiction, if any, as required by WAC **197-11-340**(2) and **197-11-355**.*

The City of Sunnyside has never incorporated WAC 197-11-355 by reference.

*(b) For DNSs issued under WAC **197-11-340**(2), agencies shall provide public notice under WAC **197-11-510** and receive comments on the DNS for fourteen days.*

The City of Sunnyside provided public notice of the MDNS on June 22, 2023, and stated

Appeal Period: This MDNS is issued under WAC 197-11-340(2). The Lead Agency will not act on this proposal for 14 days from the date of issuance. Appeals may be submitted on this proposal to the address below.

However the May 2023 Notice of Environmental Review stated

The City of Sunnyside has reviewed the proposed project for probable adverse environmental impacts and expects to issue a Determination of Nonsignificance (DNS) per WAC § 197-11-355.

FOTC did appeal the MDNS on July 6, 2023. The City of Sunnyside scheduled a hearing date for August 23, 2023. The City of Sunnyside cancelled the hearing on August 16, 2023. The city did not put the cancellation in an official document, but relied instead on an email that said:

After consultation with the City's legal team, it has been discovered that the Mitigated Determination of Nonsignificance (MDNS) issued on June 22, 2023, cannot at this time be appealed. The reason the MDNS cannot be appeal is because the MDNS only serves as an advisory statement on behalf of the City. In order to process an appeal, the MDNS is required to be tied to a development permits, such as a land use review, engineering permit, or building permit. None of those items have been issued for the site at this time, therefore the City cannot process a standalone MDNS appeal. See - Ellensburg Cement Products, Inc. v. Kittitas County, 179 Wn.2d 737 (2014).

FOTC disputed the cancellation to no avail. The City of Sunnyside did not cite rules that allow an unelected official to cancel a legally authorized hearing. In fact, the city did not point to any places in WAC 197-11 that might support the cancellation. It is inappropriate for the city to cite case law as though issuing a ruling from the bench.

FOTC disagrees with the statement *the MDNS only serves as an advisory statement on behalf of the City.* FOTC contends that environmental review means *Deciding whether a proposal has a probable significant adverse impact and thus requires an EIS (the threshold determination)* WAC 197-11-300(2)

(6) ***Public hearings and meetings.***

(a) Public hearings or meetings may be held (WAC ***197-11-535****). Notice of such public hearings shall be given under WAC* ***197-11-510*** *and may be combined with other agency notice.*

(b) In conjunction with the requirements of WAC ***197-11-510****, notice of public hearings shall be published no later than ten days before the hearing. For nonproject proposals, notice of the public hearing shall be published in a newspaper of general circulation in the general area where the lead agency has its principal offices. For nonproject proposals having a regional or statewide applicability, copies of the notice shall be given to the Olympia bureaus of the Associated Press and United Press International.*

The City of Sunnyside refused to conduct public hearings on this project. As noted, the city cancelled a public hearing of the FOTC appeal. There was no opportunity for the community to learn about risks and benefits related to the SS RNG bio-digester, thus a thwarting of the intent of the law.

WAC 197-11-510 Public notice.

(1) When these rules require notice to be given under this section, the lead agency must use reasonable methods to inform the public and other agencies that an

environmental document is being prepared or is available and that public hearing(s), if any, will be held. The agency may use its existing notice procedures.

Examples of reasonable methods to inform the public are:

(a) Posting the property, for site-specific proposals;

(b) Publishing notice in a newspaper of general circulation in the county, city, or general area where the proposal is located;

(c) Notifying public or private groups with known interest in a certain proposal or in the type of proposal being considered;

(d) Notifying the news media;

(e) Placing notices in appropriate regional, neighborhood, ethnic, or trade journals;

(f) Publishing notice in agency newsletters and/or sending notice to agency mailing lists (either general lists or lists for specific proposals or subject areas); and/or

(g) Mailing or emailing notice to any person, group or agency who has requested notice.

*(2) Each agency shall specify its method of public notice in its SEPA procedures, WAC **197-11-904** and **197-11-906**. If an agency does not specify its method of public notice or does not adopt SEPA procedures, the agency shall use methods (a) and (b) in subsection (1).*

(3) Documents which are required to be sent to the department of ecology under these rules will be published in the SEPA register, which will also constitute a form of public notice. However, publication in the SEPA register shall not, in itself, meet compliance with this section.

FOTC only became aware of the SS RNG MDNS as a result of a public records request. FOTC paid particular attention to public notices in the Yakima Herald Republic because we heard rumors about the proposed digester. We found zero notices in the Yakima Herald Republic or in the Spanish media.

To the best of our knowledge notices were sent to about twenty residences near the proposed site. Many of the recipients only speak Spanish, yet the notices were only in English. This project, if completed will have long lasting impacts on the entire county, yet most people in the county are still unaware.

The City of Sunnyside or the Port of Sunnyside placed a sign in a cornfield at the proposed site next to a highway with a 55 mph speed limit. Public notice was minimal and inadequate.

WAC 197-11-535 Public hearings and meetings.

(1) If a public hearing on the proposal is held under some other requirement of law, such hearing shall be open to consideration of the environmental impact of the proposal, together with any environmental document that is available. This does not require extension of the comment periods for environmental documents.

(2) In all other cases a public hearing on the environmental impact of a proposal shall be held whenever one or more of the following situations occur:

(a) The lead agency determines, in its sole discretion, that a public hearing would assist it in meeting its responsibility to implement the purposes and policies of SEPA and these rules; or

(b) When fifty or more persons residing within the jurisdiction of the lead agency, or who would be adversely affected by the environmental impact of the proposal, make written request to the lead agency within thirty days of issuance of the draft EIS; or

(c) When two or more agencies with jurisdiction over a proposal make written request to the lead agency within thirty days of the issuance of the draft EIS.

*(3) Whenever a public hearing is held under subsection (2) of this section, it shall occur no earlier than fifteen days from the date the draft EIS is issued, nor later than fifty days from its issuance. Notice shall be given under WAC **197-11-502**(6) and **197-11-510** and may be combined with other agency notice.*

(4) If a public hearing is required under this chapter, it shall be open to discussion of all environmental documents and any written comments that have been received by the lead agency prior to the hearing. A copy of the environmental document shall be available at the public hearing.

*(5) Comments at public hearings should be as specific as possible (see WAC **197-11-550**).*

(6) Agencies and their designees may hold informal public meetings or workshops. Such gatherings may be more flexible than public hearings and are not subject to the above notice and similar requirements for public hearings.

*(7) Public meetings held by local governments under chapter **36.70B** RCW may be used to meet SEPA public hearing requirements as long as the requirements for public hearing in this section are met. A public hearing under this section need not be an open record hearing as defined in RCW **36.70B.020**(3).*

Based on WAC 197-11-535(2) & (3) FOTC concludes that this section primarily applies to Environmental Impact Statements. However, the City of Sunnyside could have conducted public meetings or workshops to inform residents about the risks and benefits of this proposed project. Such an action would have demonstrated confidence in the intelligence and civic interest of members of the public. Absence of such meetings indicates a propensity to keep the public in the dark.

WAC 197-11-545 Effect of no comment.

.

*(1) **Consulted agencies.** If a consulted agency does not respond with written comments within the time periods for commenting on environmental documents, the lead agency may assume that the consulted agency has no information relating to the potential impact of the proposal as it relates to the consulted agency's jurisdiction or special expertise. Any consulted agency that fails to submit substantive information to the lead agency in response to a draft EIS is thereafter barred from alleging any defects in the lead agency's compliance with Part Four of these rules.*

*(2) **Other agencies and the public.** Lack of comment by other agencies or members of the public on environmental documents, within the time periods specified by*

*these rules, shall be construed as lack of objection to the environmental analysis, if the requirements of WAC **197-11-510** are met.*

It is extremely disturbing that the Yakima Regional Clean Air Agency and the Yakima Health District did not comment on the SS RNG Environmental Review. This failure to comment borders on failure to fulfill these agencies' mandated duties.

It is impossible to construct a manure methane bio-digester that produces between 800,000 and 950,000 MMBtu's of renewable natural gas per year without an impact on air quality or human health.

WAC 197-11-600 When to use existing environmental documents.

(1) This section contains criteria for determining whether an environmental document must be used unchanged and describes when existing documents may be used to meet all or part of an agency's responsibilities under SEPA.

(2) An agency may use environmental documents that have previously been prepared in order to evaluate proposed actions, alternatives, or environmental impacts. The proposals may be the same as, or different than, those analyzed in the existing documents.

Pacific Ag/Sunnyside RNG acknowledges that the company must acquire an air quality permit prior to commencing construction. When the YRACC evaluates such an application the YRCAA may incorporate the City of Sunnyside's MDNS, even though the YRCAA failed to comment on air impacts. FOTC would interpret such an action as an attempt to circumvent SEPA laws, and permit a polluting operation.

(3) Any agency acting on the same proposal shall use an environmental document unchanged, except in the following cases:

*(a) For DNSs, an agency with jurisdiction is dissatisfied with the DNS, in which case it may assume lead agency status (WAC **197-11-340** (2)(e) and **197-11-948**).*

(b) For DNSs and EISs, preparation of a new threshold determination or supplemental EIS is required if there are:

(i) Substantial changes to a proposal so that the proposal is likely to have significant adverse environmental impacts (or lack of significant adverse impacts, if a DS is being withdrawn); or

(ii) New information indicating a proposal's probable significant adverse environmental impacts. (This includes discovery of misrepresentation or lack of material disclosure.) A new threshold determination or SEIS is not required if probable significant adverse environmental impacts are covered by the range of alternatives and impacts analyzed in the existing environmental documents.

FOTC has introduced new evidence of potential adverse impacts in the forms of 1. an Evaluation of the Sunnyside RNG Traffic Impact Analysis, 2. Documentation of fires and explosions on other manure bio-digesters, 3. Reference to groundwater issues at the Port of Sunnyside, 4. Data supporting likelihood of cumulative impacts, and 5. Demographic data that demonstrates Environmental Justice concerns.

(c) For EISs, the agency concludes that its written comments on the DEIS warrant additional discussion for purposes of its action than that found in the lead agency's FEIS (in which case the agency may prepare a supplemental EIS at its own expense).

(4) Existing documents may be used for a proposal by employing one or more of the following methods:

(a) "Adoption," where an agency may use all or part of an existing environmental document to meet its responsibilities under SEPA. Agencies acting on the same proposal for which an environmental document was prepared are not required to adopt the document; or

(b) "Incorporation by reference," where an agency preparing an environmental document includes all or part of an existing document by reference.

(c) An addendum, that adds analyses or information about a proposal but does not substantially change the analysis of significant impacts and alternatives in the existing environmental document.

(d) Preparation of a SEIS if there are:

(i) Substantial changes so that the proposal is likely to have significant adverse environmental impacts; or

(ii) New information indicating a proposal's probable significant adverse environmental impacts.

New information provided by FOTC, and others strongly indicates significant adverse environmental impacts from the SS RNG project. These impacts may be direct, indirect, short term, long term, widespread and cumulative. An EIS is warranted.

(e) If a proposal is substantially similar to one covered in an existing EIS, that EIS may be adopted; additional information may be provided in an addendum or SEIS (see (c) and (d) of this subsection).

WAC 197-11-655 Implementation.

*(1) See RCW **43.21C.020**, **43.21C.030**(1), **43.21C.060**, **43.21C.075**, and **43.21C.080**.*

(2) Relevant environmental documents, comments, and responses shall accompany proposals through existing agency review processes, as determined by agency practice and procedure, so that agency officials use them in making decisions.

(3) When a decision maker considers a final decision on a proposal:

(a) The alternatives in the relevant environmental documents shall be considered.

(b) The range of alternative courses of action considered by decision makers shall be within the range of alternatives discussed in the relevant environmental documents. However, mitigation measures adopted need not be identical to those discussed in the environmental document.

(c) If information about alternatives is contained in another decision document which accompanies the relevant environmental documents to the decision maker, agencies are encouraged to make that information available to the public before the decision is made.

Since the City of Sunnyside did not evaluate alternatives to the SS RNG proposal, the city cannot comply with WAC 197-11-655

WAC 197-11-680 Appeals.

(1) ***Introduction.*** *Appeals provisions in SEPA are found in RCW* ***43.21C.060****,* ***43.21C.075*** *and* ***43.21C.080****. These rules attempt to construe and interpret the statutory provisions. In the event a court determines that these rules are inconsistent with statutory provisions, or with the framework and policy of SEPA, the statute will control. Persons considering either administrative or judicial appeal of any decision which involves SEPA at all are advised to read the statutory sections cited above.*

(2) ***Appeal to local legislative body.*** *RCW* ***43.21C.060*** *allows an appeal to a local legislative body of any decision by a local nonelected official conditioning or denying a proposal under authority of SEPA. Agencies may establish procedures for such an appeal, or may eliminate such appeals altogether, by rule, ordinance or resolution. Such appeals are subject to the restrictions in RCW* ***36.70B.050*** *and* ***36.70B.060*** *that local governments provide no more than one open record hearing and one closed record appeal for permit decisions.*

FOTC has appealed to the Sunnyside City Council three times under WAC 197-11-680(2). The first appeal was on September 22, 2023, likely beyond the short 20 day window prescribed in the Sunnyside Municipal Code section 2.72

(3) ***Agency administrative appeal procedures.***

(a) Agencies may provide for an administrative appeal of determinations relating to SEPA in their agency SEPA procedures. If so, the procedures must comply with the following:

(i) The agency must specify by rule, ordinance, or resolution that the appeals procedure is available.

(ii) Appeal of the intermediate steps under SEPA (e.g., lead agency determination, scoping, draft EIS adequacy) shall not be allowed.

(iii) Appeals on SEPA procedures shall be limited to review of a final threshold determination and final EIS. These appeals may occur prior to an agency's final decision on a proposed action.

The June 22, 2023 MDNS was a final threshold determination. Pacific Ag/Sunnyside RNG supplemented their environmental checklist with addenda on October 8, 2023. The City of Sunnyside posted a signed Notice of Addendum on November 28, 2023, with a deadline for comments of December 5, 2023.

Frankly, FOTC is confused regarding timelines for appeals, but we submit comments today to make sure we do not miss deadlines. This results in excess paperwork and excess documentation.

(iv) An agency shall provide for only one administrative appeal of a threshold determination or of the adequacy of an EIS; successive administrative appeals on these issues within the same agency are not allowed. This limitation does not apply to administrative appeals before another agency.

(v) Except as provided in (a)(vi) of this subsection, the appeal shall consolidate any allowed appeals of procedural and substantive determinations under SEPA with a hearing or appeal on the underlying governmental action in a single simultaneous hearing before one hearing officer or body. The hearing or appeal shall be one at which the hearing officer or body will consider either the agency's decision or a recommendation on the proposed underlying governmental action. For example, an appeal of the adequacy of an EIS must be consolidated with a hearing or appeal on the agency's decision or recommendation on the proposed action, if both proceedings are allowed in agency procedures. If an agency does not provide for a hearing or appeal on the underlying governmental action (either a hearing on the agency's recommendation or an agency appeal hearing after the decision is made), the agency may not hold a SEPA administrative appeal, except as allowed under (a)(vi) of this subsection.

This section says, *appeal shall consolidate any allowed appeals of procedural and substantive determinations under SEPA with a hearing or appeal on the underlying governmental action in a single simultaneous hearing before one hearing officer or body*. It does not say that appeals must be made to Superior Court as the City of Sunnyside advises.

(vi) The following appeals of SEPA procedural or substantive determinations need not be consolidated with a hearing or appeal on the underlying governmental action:

(A) An appeal of a determination of significance;

(B) An appeal of a procedural determination made by an agency when the agency is a project proponent, or is funding a project, and chooses to conduct its review under SEPA, including any appeals of its procedural determinations, prior to submitting an application for a project permit. Subsequent appeals of substantive determinations by an agency with jurisdiction over the proposed project shall be allowed under the SEPA appeal procedures of the agency with jurisdiction;

FOTC's July 6, 2023 appeal of the June 22, 2023 MDNS was mostly procedural. We believe that the City of Sunnyside and the Port of Sunnyside are project proponents based on the two years of meetings with Pacific Ag, the sale of property to Sunnyside RNG, and the extreme efforts the city and the port have exerted to move the SS RNG project forward. Based on WAC 197-11-680 (3)(a)(vi)(B) the City of Sunnyside should not have cancelled the August 23, 2023 appeal hearing.

(C) An appeal of a procedural determination made by an agency on a nonproject action; and

*(D) An appeal to the local legislative authority under RCW **43.21C.060** or other applicable state statutes.*

*(vii) If a county/city to which RCW **36.70B.110** applies provides for an administrative appeal, any such appeal of a procedural or substantive determination under SEPA issued at the same time as the decision on a project action shall be filed within fourteen days after a notice of decision under RCW **36.70B.130** or after other notice that the decision has been made and is appealable. In order to allow public comment on a DNS prior to requiring an administrative appeal to be filed, this appeal period shall be extended for an additional seven days if the appeal is of a DNS for which public comment is required under this chapter or under county/city rules adopted under SEPA. For threshold determinations issued prior to a decision on a project action, any administrative appeal allowed by a county/city shall be filed within fourteen days after notice that the determination has been made and is appealable. Nothing in this subsection alters the requirements of (a)(v) and (vi) of this subsection.*

(viii) Agencies shall provide that procedural determinations made by the responsible official shall be entitled to substantial weight.

*(b) Agencies providing for administrative appeals shall provide for a record as required by RCW **43.21C.075** (3)(c).*

(c) If an agency provides an administrative appeal procedure, that procedure must be used before anyone may initiate judicial review of any SEPA issue that could have been reviewed under the agency procedures.

The City of Sunnyside provides an administrative appeal procedure under Sunnyside Municipal Code Section 2.46 and 2.72. FOTC believes the City of Sunnyside erred by cancelling our August 23, 2023, appeal and telling us that our only option was to appeal permit decisions in Superior Court. WAC 197-11-680 (3)(c) says differently.

(4) Judicial appeals.

(a) SEPA authorizes judicial appeals of both procedural and substantive compliance with SEPA.

*(b) When SEPA applies to a decision, any judicial appeal of that decision potentially involves both those issues pertaining to SEPA (SEPA issues) and those which do not (non-SEPA issues). RCW **43.21C.075** establishes time limits for raising SEPA issues, but says that existing statutes of limitations control the appeal of non-SEPA issues. The statute contemplates a single lawsuit.*

(c) If there is a time limit established by statute or ordinance for appealing the underlying governmental action, then appeals (or portions thereof) raising SEPA issues must be filed within such time period.

The Sunnyside City Code states:

2.72.010 Appeal period.

Any appeal from any action of the City Council, City Commission or City Board, or City official or employee, whose decisions are not directly appealable to the City Council, must be brought within 20 days from the date of the effective date of the action appealed from. [Ord. 1313 § 1, 1981.]

The City of Sunnyside issued an MDNS for the SS RNG project. FOTC timely appealed. The city cancelled the appeal. After the threshold determination, SS RNG submitted changes to the environmental checklist that will affect the MDNS. FOTC may comment, but there is apparently no pathway for an appeal, according to the Sunnyside Municipal Code.

The City of Sunnyside may have designed a trap in which appeals were postponed and then prohibited due to postponement.

*(d) The notice of action procedures of RCW **43.21C.080** may still be used. If this procedure is used, then the time limits for judicial appeal specified in RCW **43.21C.080** shall apply, unless there is a time limit established by statute or ordinance for appealing the underlying governmental action. If so, the time limit for appeal of SEPA issues shall be the time limit in the statute or ordinance for the underlying governmental action. If the proposal requires more than one governmental decision that will be supported by the same SEPA documents, then RCW **43.21C.080** still only allows one judicial appeal of procedural compliance with SEPA, which must be commenced within the applicable time to appeal the first governmental decision.*

*(e) If the time limit established by statute or ordinance for appealing the underlying governmental action is less than fifteen days, then the notice of action in RCW **43.21C.080**(1) may be given by publishing once within that shorter time period, in a newspaper of general circulation in the area where the property that is the subject of the action is located, and meeting the other requirements of RCW **43.21C.080**.*

(f) If there is no time limit established by statute or ordinance for appeal, and the notice of action provisions are not used, then SEPA provides no time limit for judicial appeals. Appeal times may still be limited, however, by general statutes of limitation or the common law.

*(g) For the purposes of this subsection, "a time limit established by statute or ordinance" does not include time limits established by the general statutes of limitation in chapter **4.16** RCW.*

*(5) **Official notice of the date and place for commencing a judicial appeal.***

(a) Official notice of the date and place for commencing an appeal must be given if there is a time limit established by statute or ordinance for commencing an appeal of the underlying governmental action. The notice shall include:

(i) The time limit for commencing appeal of the underlying governmental action and SEPA issues, and the statute or ordinance establishing the time limit; and

(ii) Where an appeal may be filed.

(b) Notice is given by:

(i) Delivery of written notice to the applicant, all parties to any administrative appeal, and all persons who have requested notice of decisions with respect to the particular proposal in question; and

(ii) Following the agency's normal methods of notice for the type of governmental action taken.

(c) Written notice containing the information required by subsection (5)(a) of this section may be appended to the permit, decision documents, or SEPA compliance documents or may be printed separately.

(d) Official notices required by this subparagraph shall not be given prior to final agency action.

As noted above, FOTC is not certain of the intent of the City of Sunnyside's Notice of SEPA Addendum. FOTC could engage better if we knew whether these addenda would result in changes to the MDNS and consequently in final agency action.

The Notice of SEPA Addendum provides a window for public comments, but does not describe an appeal procedure. We understand that the lead agency has an obligation to evaluate and respond to our comments. See WAC 197-11-340 (2)(f)

WAC 197-11-910 Designation of responsible official.

*Agency SEPA procedures shall designate or provide a method of designating the responsible official with speed and certainty (WAC **197-11-906** (1)(d)). This designation may vary depending upon the nature of the proposal. The responsible official shall carry out the duties and functions of the agency when it is acting as the lead agency under these guidelines. Since it is possible under these rules for an agency to be acting as a lead agency prior to actually receiving an application for a license to undertake a private project, designation of the first department within the agency to receive an application as the responsible official will not be sufficient.*

It is FOTC's understanding that Trevor Martin from the City of Sunnyside is the responsible official for this SEPA determination.

WAC 197-11-924 Determining the lead agency.

*(1) The first agency receiving an application for or initiating a nonexempt proposal shall determine the lead agency for that proposal, unless the lead agency has been previously determined, or the agency receiving the proposal is aware that another agency is determining the lead agency. The lead agency shall be determined by using the criteria in WAC **197-11-926** through **197-11-944**.*

*(2) If an agency determines that another agency is the lead agency, it shall mail to such lead agency a copy of the application it received, together with its determination of lead agency and an explanation. If the agency receiving this determination agrees that it is the lead agency, it shall notify the other agencies with jurisdiction. If it does not agree, and the dispute cannot be resolved by agreement, the agencies shall immediately petition the department of ecology for a lead agency determination under WAC **197-11-946**.*

(3) Any agency receiving a lead agency determination to which it objects shall either resolve the dispute, withdraw its objection, or petition the department for a lead agency determination within fifteen days of receiving the determination.

*(4) An applicant may also petition the department to resolve the lead agency dispute under WAC **197-11-946**.*

*(5) To make the lead agency determination, an agency must determine to the best of its ability the range of proposed actions for the proposal (WAC **197-11-060**) and the other agencies with jurisdiction over some or all of the proposal. This can be done by:*

(a) Describing or requiring an applicant to describe the main features of the proposal;

(b) Reviewing the list of agencies with expertise;

(c) Contacting potential agencies with jurisdiction either orally or in writing.

It is FOTC's understanding that Pacific Ag/Sunnyside RNG may have approached Yakima County with this proposal prior to contacting the City and Port of Sunnyside.

WAC 197-11-92 Lead agency for governmental proposals.

(1) When an agency initiates a proposal, it is the lead agency for that proposal. If two or more agencies share in the implementation of a proposal, the agencies shall by agreement determine which agency will be the lead agency. For the purposes of this section, a proposal by an agency does not include proposals to license private activity.

(2) Whenever possible, agency people carrying out SEPA procedures should be different from agency people making the proposal.

WAC 197-11-928 Lead agency for public and private proposals.

*When the proposal involves both private and public activities, it shall be characterized as either a private or a public project for the purposes of lead agency designation, depending upon whether the primary sponsor or initiator of the project is an agency or from the private sector. Any project in which agency and private interests are too intertwined to make this characterization shall be considered a public project. The lead agency for all public projects shall be determined under WAC **197-11-926**.*

The City of Sunnyside's May 17, 2023 Notice of Environmental Review stated:

NOTICE OF ENVIRONMENTAL REVIEW This is to notify agencies with jurisdiction and environmental expertise and the public that the City of Sunnyside, Planning Division, has been established as the lead agency, under WAC § 197-11-928 for this project. The City of Sunnyside has reviewed the proposed project for probable adverse environmental impacts and expects to issue a Determination of Nonsignificance (DNS) per WAC § 197-11-355. The proposal may include mitigation measures under applicable codes and the project review process may incorporate or require mitigation measures regardless of whether an EIS is prepared. A copy of the subsequent threshold determination may be obtained by request and may be appealed pursuant to SMC Ch. 18.04.

Because this notice cited WAC 197-11-928, FOTC assumed this to be a public and private proposal. FOTC asked the City of Sunnyside several times whether it is a public and private project or a private project. The city did not answer. At a November 30, 2023 public meeting regarding the project, Harrison Pettit from Pacific Ag assured us several times that it is a private project. If this is so, then the City of Sunnyside was incorrect in

assuming the lead agency role, at least under WAC 197-11-928. FOTC asserts that the City of Sunnyside has an obligation to provide the public with accurate information.

WAC 197-11-930 Lead agency for private projects with one agency with jurisdiction.

For proposed private projects for which there is only one agency with jurisdiction, the lead agency shall be the agency with jurisdiction.

FOTC has asked the City of Sunnyside to list agencies with jurisdiction for the SS RNG project. The city has not answered.

* * * * * * * *

There are errors in the documents posted for this project:

- In the November 16, 2022, and May 17, 2023 Notice of Environmental Reviews the City of Sunnyside stated:

The City of Sunnyside has reviewed the proposed project for probable adverse environmental impacts and expects to issue a Determination of Nonsignificance (DNS) per WAC § 197-11-355.

But the City of Sunnyside has not incorporated WAC 197-11-355 by reference.

- In the November 16, 2022, and May 17, 2023 Notice of Environmental Reviews the City of Sunnyside stated:

This is to notify agencies with jurisdiction and environmental expertise and the public that the City of Sunnyside, Planning Division, has been established as the lead agency, under WAC § 197-11-928 for this project.

But WAC 197-11-928 refers to public and private projects. Sunnyside RNG claims this is a private project.

- Tax Parcel Numbers are listed as:

    - Notice of Environmental Review TAX PARCEL NUMBER(S): 220901-13001, -44401, -41404
    - Mitigated Determination of Non-Significance Parcel Number(s): 220901-13001, -44401, & -41404
    - Notice of Appeal Cancellation TAX PARCEL NUMBER(S): 220901-13001, -44401, -41404
    - Notice of SEPA Addendum TAX PARCEL NUMBER(S): 22090-141405 & 220901-41406 (Previously 220901-13001, -44401, - 41404)

- When did these changes occur? FOTC asks because we have spent many, many hours trying to make sense of the property location and zoning.

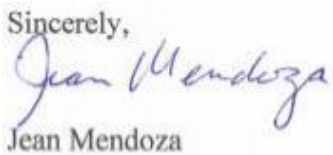
- Many related documents list two different File Numbers: SEPA-2022.0200 & SEPA 2023.0200 for the same project

- The October 8, 2023 Addendum Letter from Sunnyside RNG to the City of Sunnyside references File Number 2022.0200

- The October 8, 2023 Addendum Letter from Sunnyside RNG to the City of Sunnyside references Exhibit B, *A Cultural Resources Survey for the Sunnyside RNG project*. This document has not been posted for public view.

- The October 8, 2023 Addendum Letter from Sunnyside RNG to the City of Sunnyside also identifies Exhibit B as a *Traffic Impact Analysis*

- The signature date for this letter is November 8, 2023, while the heading date for the letter is October 8, 2023



- The November 28, 2023 Notice of SEPA Addendum says:

  There is a 14-day comment period for this review. This may be your only opportunity to comment. All written comments received by 5:00 p.m. on December 5, 2023. Please reference file numbers (SEPA-2022.0200) and applicant's name (Sunnyside RNG) in any correspondence you submit.

  We are not sure this is the correct File Number.

The Friends of Toppenish Creek appreciate this opportunity to comment on SEPA review for the SS RNG project. We request clarification on next steps, specifically the appeal process as interpreted by the Lead Agency, the City of Sunnyside.

Sincerely,

Jean Mendoza

Executive Director, Friends of Toppenish Creek

FOTC Comments regarding the Sunnyside RNG Traffic Impact Analysis
August 28, 2023

These comments are based on a reading of a document entitled Sunnyside RNG Traffic Impact Analysis[1] that Friends of Toppenish Creek received on August 24, 2023, through a public records request.

When the City of Sunnyside issued a mitigated determination of non-significance (MDNS) for the Sunnyside Renewable Natural Gas (RNG) project, on June 22, 2023, that determination stated, "A traffic report is on file with the City of Sunnyside and has been reviewed by WSDOT" and "This information (including all environmental documentation and a traffic study) is available to the public upon request and can be examined at our office during regular business hours."[2]

But the date of publication for the Sunnyside RNG Traffic Impact Analysis is July 10, 2023.

The City of Sunnyside posted a Notice of Environmental Review for SEPA analysis of the SS RNG project on May 17, 2023. Sunnyside posted the mitigated determination of nonsignificance (MDNS) on June 22, 2023. The Traffic Impact Analysis was not published until July 10, 2023, and was not shared with FOTC until August 24, 2023. It is almost impossible to form conclusions about a project within the time frames for comment and appeal without adequate data.

This document only looks at intersections within the City of Sunnyside. It does not address potential traffic issues in Yakima County. According to FOTC calculations, based on Figure 4 in the Traffic Impact Analysis, there would be 36 truck trips per day from the south on the Mabton Sunnyside Road. There is no discussion of the impact from this truck traffic.

Most of the manure that would be trucked to the SS RNG facility would be transported on Yakima County roads. Based on measurements from Figure 4 in the Traffic Impact Analysis there would be over 1,500 miles of truck traffic every day, and most would be on county roads.

Currently 17.6% of Yakima County property taxes apply to county roads. According to the 2023 Budget for Yakima County, the year began with a fund balance of $5,000,000 and will end with a fund balance of $1,302,797. Expected revenues are $43,850,841, while expected expenditures are $47,548,040.[3]

The WA State Association of Counties says.[4]

> *The unsustainable reality is: County transportation budgets are going backward. Counties' transportation dollars, when adjusted for inflation, are fewer than they were twenty years ago. Existing limitations on counties' ability to keep pace with growing obligations have created an annual transportation funding gap of at least $1 billion.*

Road and traffic experts tell us that wear and tear on roadways is over 2,500 greater for an eight axle truck compared to a two axle automobile.[5, 6]

Calculating the emissions from large trucks traveling 1,500 miles per day is beyond FOTC expertise. But we know that traffic emissions contribute to air pollution. In our opinion the Yakima Regional Clean Air Agency was obligated to comment after receiving the SS RNG Notice of Environmental Review – See RCW 43.21C.030(2)(d) which says, "Prior to making any detailed statement, the responsible official shall consult with and obtain the comments of any public agency which has jurisdiction by law or special expertise with respect to any environmental impact involved."

Thank you for reading.

Debt	548,548	162,346	160,000	0
Operating Transfers Out	156,962	158,465	158,961	155,161
Total Expenses	23,396,127	27,745,678	37,245,969	47,548,044
Ending Fund Balance	6,956,899	3,264,596	2,823,847	1,302,797
Total Budget	30,353,026	31,010,274	40,069,816	48,850,841

Program Description:

The County Road Division of the Public Services Department is responsible for the Maintenance, Preservation and Improvement of 1,633 miles of roads, 308 federally inventoried bridges and 267 short-span bridges. The County Road Division is also responsible for the administration, accounting and right-of-way management to support these primary activities.

Major Objectives:

- Maintain and Preserve the County's road and bridge inventory is a condition that meets the transportation demands places on it.
- Sustain a Safety Improvement Program, including enhanced traffic law enforcement, in order to ensure the safety of persons traveling on Yakima County roads.
- Plan, Design and Construct those vital transportation improvements identified in the adopted annual road program and Six Year Transportation Improvement Program.
- Aggressively pursue grants, loans and other innovative financing opportunities required to sustain the road and bridge improvements necessary to support the continued economic vitality of the region.
- Sustain a Maintenance Management system in order to ensure the long term, economical and efficient maintenance of County roads.
- Implement organizational and operational programs including: providing adequate levels of staff, developing employee training opportunities, and streamlining development review processes.
- Maintain and update countywide transportation plan.

Revenue/Expenditure Comment:

Major sources of revenue for the County Roads includes: up to $2.25 per $1,000 of assessed value property tax in the unincorporated areas of Yakima County. For 2022, the Maximum Lawful Road levy is estimated to be $16,115,000. For the Preliminary Budget, a Levy Shift of $2,200,000 is assumed, lowering the Road Levy to $13,967,000, with a resulting Levy Rate of $1.65 per $1,000 of assessed valuation. Other major fund sources are: direct allocation of the County's share of the State Gas Tax, and funds from State and Federal Transportation Grants.

County Road (cont.)

County Road spending priorities are: Maintaining and preserving the existing system, providing targeted improvements calculated to improve the safety of County roads, enhancing the economic viability of the region through focused investment in transportation improvements, and provide for enhanced quality of life for Yakima County citizens.

The County Road fund also focuses on traffic Safety by funding the cost of three and one-half Sheriff's Deputies under an annual contract between the County Sheriff and Board of County Commissioners. Four Deputies are assigned to a Traffic Enforcement Squad but are available to answer higher priority criminal and life safety calls. Implementation of the contract and performance measurements are identified in a Memorandum of Understanding between the County Engineer and the County Sheriff. For budget purposes a 2022 County Road expenditure amount of $535,387 for traffic policing is included in the Budget.

December 19, 2023

Trevor Martin, AICP
Community & Economic Development Director, City of Sunnyside
Community and Economic Development Department
818 E. Edison Ave.
Sunnyside, WA 98944

Dear Mr. Martin:

Please accept these additional comments from the Friends of Toppenish Creek regarding amendments to the City of Sunnyside mitigated determination of non-significance (MDNS) for the proposed Sunnyside Renewable Natural Gas (SS RNG) digester project - SEPA 2022-0200 or SEPA 2023.0200. We submit these comments to further support our position that the SS RNG project needs an Environmental Impact Statement (EIS).

FOTC believes that the Environmental Checklist submitted to the City of Sunnyside in December 2022 is outdated, incomplete, and insufficient to justify an MDNS for the following reasons:

Page 3/13

The proposed project is located on 50 acres of land just South of the City of Sunnyside within the Port of Sunnyside Midvale Industrial Park, and adjacent to the Sunnyside Mabton Hwy# 241.

Comment: To our understanding the Port of Sunnyside is within the Sunnyside City limits. Thus, the proposed manure methane plant would be located within the Sunnyside City limits.

Digestate and other residues produced at the plant will be carefully managed

Comment: This statement is not sufficiently specific to allow any kind of analysis.

The subject properties are identified as Parcel# 220901-41404, # 220901- 14007 and the eastern half of# 220901-13001.

Comment: The June 22, 2023 MDNS listed the Parcel Numbers as Parcel Number(s): 220901-13001, -44401, & -41404 which are not exactly the same. The City of Sunnyside has since revised the parcel numbers on the MDNS to read 22090-141405 & 220901-41406.

Page 4/13

Digestate NH3 emissions are modeled under the daily limit, and are additionally exempt from regulation pursuant to RCW 70A.15.4540.

RCW 70A.15.4540 reads:

The department shall not regulate ammonia emissions resulting from the storage, distribution, transport, or application of ammonia for use as an agricultural or silviculture fertilizer.

Comment: SS RNG states that some of the digestate will be used as animal bedding and compost. Thus RCW 70A.15.4540 does not apply.

Comment: Proposed modeling under a daily limit has not been provided in this Environmental Checklist.

Are there any off-site sources of emissions or odor that may affect your proposal? If so, generally describe. ***Background concentrations will be accounted for in the Air Permit.***

Comment: Pacific Ag failed to document emissions from Windmill Mushrooms, Nutrien Solutions, and the City of Sunnyside Waste Water Treatment Plant, all of which would contribute to cumulative air pollution in the area. Are emissions from these sources considered background?

b. Ground Water:

2) Describe waste material that will be discharged into the ground from septic tanks or other sources, if any (for example: Domestic sewage; industrial, containing the following chemicals . .. ; agricultural; etc.). Describe the general size of the system, the number of such systems, the number of houses to be served (if applicable), or the number of animals or humans the system(s) are expected to serve. ***No waste will be discharged to the ground.***

c. Water runoff (including stormwater): 1) Describe the source of runoff (including storm water) and method of collection and disposal, if any (include quantities, if known). Where will this water flow? Will this water flow into other waters? If so, describe.

Stormwater runoff will be retained on site and infiltrated into the ground at various locations including a potential stormwater pond. This water will not flow into other waters.

Comment: If stormwater is infiltrated into the ground, then any waste in the stormwater that is *infiltrated into the ground* will reach the aquifer. Any spilled manure on site would contaminate stormwater. Flow from groundwater to surface waters, such as the already contaminated Sulphur Creek Wasteway is well documented. Pacific Ag has not described lining for ponds and lagoons at the site.

Page 8/13

Describe special emergency services that might be required. Standard emergency and fire services, as well as potentially confined space rescue. ***Other special health and safety planning is underway and will be confirmed with emergency services and County Health Department. Standard emergency services equipment includes self-contained breathing apparatus (SCBA) appropriate for potential exposure.***

Comment: FOTC submitted a public records request to Yakima Emergency Management Services in November 2023, asking for information about conversations between Pacific Ag and SS RNG regarding preparations for potential explosions and fires. Yakima EMS replied that there have not been any such conversations.

Page 9/13

1) *Will the proposal affect or be affected by surrounding working farm or forest land normal business operations, such as oversize equipment access, the application of pesticides, tilling, and harvesting? If so, how:* ***No, the proposal is consistent with uses in the surrounding area.***

Comment: FOTC disagrees.

In September 2022 Pacific Ag told the Port of Sunnyside that SS RNG would: *Produce an organic digestate that can be used as fertilizer, livestock bedding and compost*.

And: *Recycles manure and kills odors and pathogens while producing a renewable fuel and soil products.*

1. FOTC maintains that mesophilic and even thermophilic process are insufficient to kill pathogens in the digestate. Pacific Ag has not described any other mechanism for killing pathogens.

2. Digestate would presumably be applied to cropland in South Yakima County. This digestate would likely contain pesticides, herbicides, and veterinary pharmaceuticals from manure and crop residues. Research from John Hopkins University[1] tells us that anaerobic digesters do not always degrade these chemicals.

The John Hopkins team studied 20 chemicals after anaerobic digestions, namely:

Fungicides: boscalid, carbendazim, difenoconazole, pyraclostrobin, & tebuconazole

Insecticides: carbaryl, chlorpyrifos, diflubenzuron, & malathion

[1] Brueck, Christopher L., et al. "Assessing the fate of antibiotics and agrochemicals during anaerobic digestion of animal manure." *Science of the Total Environment* 856 (2023): 159156. https://www.sciencedirect.com/science/article/am/pii/S0048969722062556

Herbicides: dicamba, imazapyr, & triclopyr

Antibiotics: ceftiofur, erythromycin, lincomycin, monensin[2], sulfamethazine, sulfamethoxazole, trimethoprim

Feed Additive: ractopamine.

Nine of the twenty - boscalid, carbendazim, difenoconazole, imazapyr, lincomycin, monensin,[2] ractopamine, sulfamethazine, and tebuconazole - did not degrade during digestion.

The study did not evaluate toxicity of the transformation products. The study suggested the possibility of development of pesticide and antibiotic resistance during anaerobic digestion.[3,4]

While this work fills previous knowledge gaps, it also emphasizes that additional work is needed to evaluate the fate of AD-derived TPs (transformation products) as they pass through manure management systems and after field application where they are exposed to alternate microbial and redox environments. It is unclear whether these TPs will retain the antibiotic or pesticidal properties from their parent compounds, potentially contributing to the development of pesticide and antibiotic resistances.

3. Studies describe negative impacts on earthworm populations when anaerobic digestate is applied as fertilizer.[5,6] At a minimum, farmers who might accept and use digestate, farming neighbors, the public, and potential compost customers should be informed of this potentiality.

The issues are complicated. With no disrespect, FOTC states that the Sunnyside Department of Commerce and Economic Development lacks the expertise to evaluate the many potential impacts from one of the largest manure methane plants in the nation on the small City of Sunnyside and the surrounding area. An Environmental Impact Statement is necessary.

White Swan, WA 98952

July 6, 2023

Planning & Community Development
818 East Edison Avenue
Sunnyside, Washington 98944

Dear City of Sunnyside:

This is an appeal of the City of Sunnyside's Mitigated Determination of Non-Significance (MDNS) for a proposed manure bio-digester to be located in the vicinity of 2711 and 334 Sunnyside Mabton Highway. The SEPA Number is SEPA-2022.0200 and the applicant is Sunnyside Renewable Natural Gas (RNG). If this letter is not sufficient, please provide instructions with the proper format and pathway so we can submit our appeal in the prescribed manner.

Friends of Toppenish Creek (FOTC) is a 501 C (3) non-profit group located in Yakima County, mailing address 3142 Signal Peak Road, White Swan, WA. We make this appeal because the proposed SS RNG project will:

1. Increase public expenditures to:
    a. upgrade and maintain state and county roadways used to transport materials to and from the proposed operation.
    b. Incentivize one form of manure management that is arguably more costly than alternative methods.[1, 2]
2. Inflict manure spills on residents who live near the roads traveled by vehicles that transport manure to the proposed operation. Manure spills on public roadways, even on areas where children wait for school busses, are well known to the people who live near concentrated animal feeding operations (CAFOs).
3. Increase air pollution in South Yakima County by potentially increasing the number of milk cows in the area, by increasing air emissions from vehicles that transport materials to and from the proposed operation, by increasing emissions of toxic air pollutants[3] from the proposed operation.
4. Increase risk of explosions and fires at the Port of Sunnyside without ensuring adequate safety precautions. Assurances in the documents we have reviewed are vague and unenforceable. Methane leaks from improperly maintained operations are commonplace and risks increase as time passes and equipment ages.[4] Although the chances of explosions are low, the consequences of explosions when they occur can be deadly.

5. Increase groundwater pollution at the Port of Sunnyside. A LYV GWMA monitoring wells with one of the highest LYV nitrate concentrations is on the Port of Sunnyside.[5] There are insufficient guarantees that stormwater and wastewater from the facility will not leach into the already contaminated aquifer.

The MDNS is premature and incomplete because:

1. Interested parties, such as FOTC, did not receive notice of the proposed SEPA review through public notices in the media, or by notification from agencies that are aware of our concerns.
2. Interested parties, such as FOTC, have not received and have not been able to review relevant documents cited in the MDNS.
3. There is no documentation of conversations with the Yakima Health District, the agency tasked with protection of public health in Yakima County. Without this input it is not possible to know how this project will:
    a. Impact those who live in the immediate vicinity through increases in toxic air pollutants such as ammonia and hydrogen sulfide at the fenceline, and exposure to manure pathogens.
    b. Impact those who live distant from the proposed facility through increases in greenhouse gasses including nitrous oxide, increases in criteria air pollutants including fine particulate matter and ozone, and increases in toxic air pollutants including ammonia and hydrogen sulfide.
4. The SEPA checklist states on page 3/13, "Digestate and other residues produced at the plant will be carefully managed, along with strict wastewater management, emissions management, odor control and other state-of-the art practices." This statement provides insufficient information for the public to evaluate adequacy of the "state-of-the art practices." Those proposed practices must be identified so citizens can evaluate whether all Reasonable Available Control Technology (RACT) will be achieved.[6, 7, 8, 9]
5. The SEPA checklist does not estimate the cumulative impacts when a manure bio-digester is located next to a mushroom factory with known air emissions and odor problems that the Yakima Regional Clean Air Agency (YRCAA) refuses to address.[10]
6. The SEPA checklist states that the digestate lagoon will be lined. The checklist does not state whether this will be a clay liner or a synthetic liner. The checklist does not provide permeability criteria for proposed lagoon liners.
7. The SEPA checklist does not provide parameters for a "gas tight" cover for the digestate lagoon. How much gas will escape from the proposed cover?
8. The SEPA Checklist asks: "What types of emissions to the air would result from the proposal during construction, operation, and maintenance when the project is completed? If any, generally describe and give approximate quantities if known?" The application answers this question for construction. What about operation and maintenance? Manure bio-digesters increase conversion of organic nitrogen to ammonia as part of routine

operations.[11] This information is available to the applicants and should have been answered in the SEPA checklist.

9. The SEPA checklist does not quantify the amount of ammonia, hydrogen sulfide, volatile organic compounds, and particulate matter that will be released into the atmosphere during on farm production of the manure that will be processed to extract RNG.
10. The SEPA checklist does not quantify the amount of nitrogen oxides (NOx) that will be released into the atmosphere during transport of manure to the facility and transport of digestate from the facility.
11. The SEPA checklist does not quantify the amount of ammonia, hydrogen sulfide, volatile organic compounds, and particulate matter released into the atmosphere by digestate from the operation, both at the site and after transport offsite.
12. Regarding air emissions the SEPA checklist states: "Background concentrations will be accounted for in the Air Permit." The area surrounding the Port of Sunnyside already has problems with air emissions and odor. Using the current air quality as a baseline is not the same as defining a baseline with healthy air. Adding emissions from a manure bio-digester could push air quality at the fenceline above standards for human health.
13. The SEPA checklist states on page 4, "These emissions quantities are being refined currently as part of the Clean Air Permit Application with Yakima County." This is likely incorrect. To the best of our knowledge an application for an air quality permit has been withdrawn and has not been resubmitted. The public cannot form an opinion about air quality risks without the information in an up to date air quality permit application.
14. There are many unanswered questions, such as:
    a. Will manure transported to the digester be covered or open to the air?
    b. What size and type of trucks will transport cellulosic materials and manure?
    c. What is the anticipated weight of each incoming truckload?
    d. Will the SS RNG ask for an overweight exemption?
    e. Will truck drivers possess Commercial Drivers Licenses (CDLs) or will the SS RNG use the agricultural exemption for drivers who transport agriculture goods?
    f. What air monitoring will be installed?
    g. Which air emissions will be monitored?
    h. What is the predicted composition of the tail gas that is vented to the atmosphere?
    i. Will there be fenceline monitoring to provide early warning if leaks pose a danger to neighbors?
    j. What system will be in place to detect significant methane leaks within the plant at the earliest moments?
    k. Why is there only one flare, as opposed to five flares in earlier plans?
    l. What emergency management and firefighting protocols will be in place? [12, 13]
    m. What equipment, training, alarms, will be used to address potentially dangerous levels of methane, hydrogen sulfide, and other air contaminants on the site?

n. How long will the digesters operate in the mesophilic range? How long will the digesters operate in the thermophilic range? This makes a difference in how many pathogens are destroyed by digestion.
o. How will settled solids be removed from the digesters, and what is the planned process?
p. How much digestate will be stored on site at any given time?
q. How will the solid fraction of digestate be stored prior to transport?
r. How will liquid digestate be transported off site?
s. Which rules, regulations and permitting apply to the proposed lagoon?
t. What are the anticipated emissions from the solid fraction of digestate and how will they be managed?
u. Will liquid and solid digestate transported away from the project be covered or open to air?
v. How will dairies store digestate during winter months when they cannot apply it to fields as fertilizer?
w. Are there any requirements in place that ensure digestate will be applied to fields at agronomic rates?
x. Will the facility have sufficient insurance to compensate the families of workers who might be injured or die in a fire or explosion on the facility?
y. What protocols will be in place to ensure proper maintenance as the equipment ages?[14]
z. Will the proposed RNG facility digest the carcasses of unwanted farm animals?
aa. Who will monitor the facility to ensure that daily operations are conducted in a safe manner, and how will they do this?
bb. Will this SEPA review be used when the Yakima Regional Clean Air Agency decides whether to issue an air quality permit? If so, the early determination of mitigated non-significance makes it difficult to meet the requirements for public involvement for issuing an air permit.
cc. Each of these questions must be answered before the public has enough information to provide input. Therefore an Environmental Impact Statement is needed.

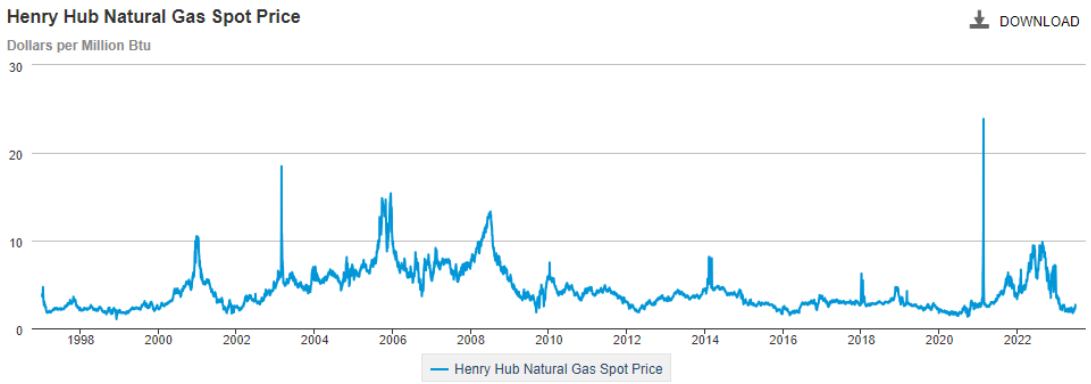
15. The SEPA Checklist states on page 9, "The project will generate direct and indirect tax revenue of approximately $6 million annually to support schools and other community services." But there is no detail. Meanwhile, this project is eligible for tax exemptions under RCW 82.34, RCW and RCW 82.08. The public needs better information.

Here are important facts related to risks and benefits from the proposed Sunnyside Renewable Natural Gas bio-digester.

1. According to the EPA[15] manure management is responsible for 8% of U.S. methane production and enteric fermentation is responsible for 25%. This means that for every ton

of methane processed by anaerobic digestion, three tons are emitted into the atmosphere by the animals and escape capture.

   a. Addition of a few thousand cows to the approximately 90,000 already in the area will likely increase methane emissions by enteric fermentation to a point where increased enteric emissions cancel out any proposed benefits from manure digestion.
   b. Reduction in methane emissions equal to those touted for manure digesters could be achieved at lower cost by not storing cow manure in lagoons, by promoting alternative methods of manure management.



2. Some experts point out that farmers may enjoy more profits from processing manure methane than from the sale of milk. Hoards Dairyman [16] says:

   a. *The profit generated by manure and energy is a new dynamic for dairy farms. A common arrangement is for a third party to invest in the digester and form an agreement with one or more dairy farms for a supply of manure. These contracts can be for 10 to 15 years or longer and pay $80 to $100 per cow per year or more. For a 3,500-cow dairy, that means $350,000 per year or 40 cents per hundredweight based on an 80 pound per day tank average*.
   b. This may be good for some (but not all) dairies, but officials should conduct a comprehensive Environmental Impact Statement to evaluate associated costs in water pollution and air pollution and human health when the number of cows increases.

3. Manure bio-digesters increase emission of some air pollutants. Manure bio-digesters produce and release carbon dioxide, a greenhouse gas. Manure bio-digesters convert organic nitrogen into ammonia and release it into the ambient air.[1, 2]
4. Proponents of alternative manure management argue that, compared to anaerobic digestion, manure solids separation provides a larger reduction in greenhouse gas emissions at lower costs. California research[1] says:

   > *While digestate left after anaerobic digestion is more stable than the original manure feedstock, it can still produce methane and other gaseous emissions from the biological decomposition of residual nutrients. Holly et al. reported that mesophilic anaerobic digestion reduces the emissions of CH_4 but increases the emissions of both NH_3 and N_2O during the storage of digestate. They found that solid–liquid separation, using a screw press, was more effective in reducing the emissions of methane than anaerobic digestion due to the low performance of the digester. Compared with storing raw manure, the reduction of methane emissions from storage was 25%, 46%, and 68% for the anaerobic digestion alone, solid separation alone, and anaerobic digestion followed by solid–liquid separation.*

5. Almost all LYV dairies already have some form of manure solids separation. The SS RNG proposal does not describe changes that must occur on LYV dairies to produce the slurry required to feed the proposed digester.
6. The plan calls for up to 140 round trips per day by heavy duty trucks hauling manure and cellulosic material to the facility and trucking digestate back to the farms. To understand the total impact of an RNG operation officials must conduct an Environmental Impact Statement that calculates the amount of diesel fuel burned by the trucks and the amount of NOx and other emissions produced by transport. NOx combines with volatile organic compounds to produce ozone, a criteria pollutant that is not mentioned in the SS RNG SEPA checklist.
7. In the spring of 2022 Monitoring Well PS-MW-9, LYV-PS-031, located on the Port of Sunnyside property, had nitrate levels at 84 mg/L according to Ecology's Environmental Information Management Data Base.[5]
8. By FOTC calculations it takes 21,855,360 m^3 of methane to produce 800,000 MMBTU of RNG.[17] And it takes about 50,000 milk cows to produce this much manure methane if each cow produces 125 lbs of manure a day.[18] It takes over 59,000 milk cows to achieve 950,000 MMBTU of RNG.
9. Economic data provided in the SEPA checklist only looks at current numbers. But the price of natural gas fluctuates widely over time.[19]
    a. Between 1994 and 2023 the spot price for natural gas ranged from $1.44 per MMBTU (Dec. 7, 1998) to $23,86 per MMBTU (Feb. 16, 2021).
    b. Between 2000 and 2023 the spot price for natural gas ranged from $1.74 per MMBTU (March 2, 2020) to $23,86 per MMBTU (Feb. 16, 2021).

10. What are the implications for the Port of Sunnyside if profits from natural gas decline and the operation is no longer viable?
11. Under Washington's Climate Commitment Act, "Offset projects include things such as reforestation, planting trees in urban areas, and capturing methane on dairy farms. And because greenhouse gas emissions affect the entire atmosphere, even projects in another country can help us fight climate change here in Washington." [20] Profits from selling

offset credits will decline over time. Offsets are not a reliable source of income for bio-manure RNG facilities in the long term.

12. Mismanagement of biogas facilities happens.[21]

    The U.S. Environmental Protection Agency (EPA) and Nebraska Department of Environment and Energy conducted multiple inspections of the Big Ox Energy facility in 2017 and 2018. The agencies found that the facility was releasing hazardous amounts of biomass and biogas. On at least 16 occasions between 2017 and 2019, biomass released from the digesters went over the sides of the facility's roof and onto the ground where it mixed with stormwater, resulting in discharges to adjacent properties and into nearby water bodies. In 2018, a facility malfunction resulted in 80,000 gallons of biomass overflowing from the digesters. These discharges resulted in emissions of biogas, an extremely hazardous substance. Air monitoring conducted by EPA determined that the facility was emitting methane at levels that were flammable and hydrogen sulfide in amounts that could result in injury or death from inhalation.

    Violations included:

    - *Failure to design and maintain a safe facility*
    - *Improper maintenance of digesters*
    - *Failure to control accidental releases of extremely hazardous substances*
    - *Violations of air emission standards*
    - *Causing the Sioux City wastewater treatment plant to exceed water quality limits*
    - *Failure to comply with EPA- and state-issued compliance orders*
    - *Unauthorized discharges into local water bodies*
    - *Failure to comply with air and water permits*

The Friends of Toppenish Creek ask officials not to rush to approval of this project that would change the landscape of South Yakima County for years to come. Please be careful and thoughtful when making these decisions.

Thank you for considering our concerns.

A gas pipeline incident occurs somewhere in the U.S. approximately every 40 hours. From 2010 through nearly the end of 2021, almost 2,600 pipeline incidents related to the release of gas occurred in the United States that were serious enough to be reported to the federal government, 328 of which resulted in explosions. Those explosions and fires killed 122 people and injured 603.

24 Dairies between 12 and 24 miles from the facility

Comments re Addendum to Sunnyside Renewable Natural Gas (SS RNG) SEPA document

Friends of Toppenish Creek is a 501 C (3) non profit group incorporated under the laws of Washington State and located in Yakima County. FOTC submits the following comments regarding an addendum submittal to a June 2023 SEPA review and mitigated determination of non-significance (MDNS) for a proposed Renewable Natural Gas (RNG) bio-digester at the Port of Sunnyside. The City of Sunnyside Notice of SEPA Addendum asked commenters to reference SEPA 2022.0200. We are not sure whether this is correct, or whether SEPA 2022.0200 exists.[1] The correct file number may be SEPA 2023.0200.

It is difficult to comment intelligently on this addendum submittal because the notice omits so much content. For example, the addendum includes a February 2023 New Source Review (NSR) application from Sunnyside RNG to the Yakima Regional Clean Air Agency (YRCAA) but omits the response from the YRCAA that rejected the application and requested more information.

FOTC believes that an MDNS should not have been issued until the City of Sunnyside and the public had the opportunity to review information on air emissions and traffic impacts. The MDNS was issued on June 22, 2023, but a Traffic Impact Analysis (TIA), that is part of the November 23, 2023 addendum letter, is dated July 10, 2023.

The Yakima Regional Clean Air Agency, as the agency with expertise on air, failed to comment on the May 2023 SEPA Review, as required by RCW 43.21C and WAC 197-11, and especially WAC 197-11-030, WAC 197-11-060(4), and WAC 197-11-502(2).

The City of Sunnyside did not have sufficient information to conclude no environmental impacts, and the public did not have sufficient information to comment intelligently on the May 2023 Environmental Review. The resulting MDNS is invalid due to withheld and/or insufficient information. See WAC 197-11-335, WAC 197-11-340(3), WAC 197-11-080.

* * * * * *

[1] FOTC does not find SEPA 2022.0200 in Ecology's State Environmental Policy Act (SEPA) Register at https://apps.ecology.wa.gov/separ/Main/SEPA/Search.aspx?SearchText=City%20of%20Sunnyside&SearchFields=All&County=YAKIMA&PageSize=10&SortColumn=LeadAgencyAscending&Page=17

According to a presentation by Pacific AG to the Port of Sunnyside[2] on September 6, 2022, the Sunnyside RNG facility could be "one of the largest ag waste anaerobic digesters in the nation."[3]

Realistically, how can "one of the largest waste anaerobic digesters in the nation" not have an impact on the environment?

The SS RNG project would:

- Produce between 800,000 & 950,000 MMBTUs of Renewable Natural Gas a year
- Produce and store methane, a flammable and explosive gas, in tanks with membrane covers
- Transfer the natural gas to a major pipeline
- Move 140 truckloads of manure every day from dairies to the digester
- Store digestate in stacks at the digester site and on farms
- Store liquid effluent from the digester in lagoons
- Spread digestate onto crop fields. There is insufficient information to determine the composition of the digestate and potential impacts on soil health and greenhouse gas emissions.

* * * * * * *

Manure bio-digesters are known to experience spills and explosions.[4] These adverse impacts are not expected to occur, but when they do occur the impacts are grave. Washington law accounts for this in WAC 197-11-794 (2).

FOTC has requested more information regarding fires and spills from Pacific AG, Sunnyside RNG, and Yakima County Emergency Services. The City of Sunnyside should not take further action on the SS RNG MDNS until this information arrives, and answers satisfy potentially impacted people.

* * * * * * *

FOTC believes the City of Sunnyside violated many sections of Washington SEPA law when the city issued the June 22, 2023 MDNS. These alleged violations are listed below. FOTC believes that the MDNS should be rescinded pursuant to WAC 197-11-340(3), a determination of non-significance (DNS) should be issued, and an Environmental Impact Statement (EIS) completed. Conducting a thorough EIS is the only way to adequately determine the environmental consequences of constructing such a large digester.

---

[2] See Attachment 1

[3] Harrison Pettit from Pacific Ag said this was not true at a public meeting in Sunnyside on November 30, 2023.

[4] See Attachment 2

WAC 197-11-030

Policy.

(1) The policies and goals set forth in SEPA are supplementary to existing agency authority.

(2) Agencies shall to the fullest extent possible:

(a) Interpret and administer the policies, regulations, and laws of the state of Washington in accordance with the policies set forth in SEPA and these rules.

(b) Find ways to make the SEPA process more useful to decision makers and the public; promote certainty regarding the requirements of the act; reduce paperwork and the accumulation of extraneous background data; and emphasize important environmental impacts and alternatives.

(c) Prepare environmental documents that are concise, clear, and to the point, and are supported by evidence that the necessary environmental analyses have been made.

(d) Initiate the SEPA process early in conjunction with other agency operations to avoid delay and duplication.

(e) Integrate the requirements of SEPA with existing agency planning and licensing procedures and practices, so that such procedures run concurrently rather than consecutively.

(f) Encourage public involvement in decisions that significantly affect environmental quality.

(g) Identify, evaluate, and require or implement, where required by the act and these rules, reasonable alternatives that would mitigate adverse effects of proposed actions on the environment.

The City of Sunnyside did not, to the fullest extent possible, *Interpret and administer the policies, regulations, and laws of the state of Washington in accordance with the policies set forth in SEPA and these rules.* Sunnyside did not compel the Yakima Regional Clean Air Agency to provide comments on air impacts from:

- Potential leaks at the digester site
- Transport of manure and digestate
- Leaks in pipes that transport natural gas
- 140 round trip truck trips per day
- Storage of manure and digestate in stacks and lagoons
- Spreading and spraying digestate on crop fields

The City of Sunnyside did not *promote certainty regarding the requirements of the act.* Sunnyside sent conflicting messages to the public by telling the public that an appeal was authorized, improperly stating the appeal would be a closed appeal, scheduling an appeal, and then canceling the appeal. Sunnyside did not respond to reasonable questions regarding the proposed RNG project.[5]

[5] See Attachment 3 FOTC Request for the City of Sunnyside to reconsider an MDNS for the Sunnyside RNG project. The City did not answer our questions.

The City of Sunnyside did not *emphasize important environmental impacts and alternatives.* Sunnyside did not explore or list alternatives to the project or citing of the project. Sunnyside did not describe potential air impacts or potential impacts to ground and/or surface waters at the Port of Sunnyside where monitoring wells have high levels of nitrate[6] and the Sulphur Creek Wasteway traverses the area. The City of Sunnyside did not address the potential for fires and explosions.

There were no analyses to prove statements by the project proponent, Pacific Ag/Sunnyside RNG, that the project would generate millions in tax dollars. There was no analysis of costs to tax payers in the form of subsidies, wear and tear on roadways, and decreased property values.

The City of Sunnyside did not *integrate the requirements of SEPA with existing agency planning and licensing procedures and practices, so that such procedures run concurrently rather than consecutively.* Instead Sunnyside issued an MDNS and then told FOTC that we could not appeal the MDNS until a later time after Pacific Ag applied for a permit.

The City of Sunnyside did not *encourage public involvement.* Instead, the city made it difficult for the public to be involved by not posting notices in newspapers, by not translating notices into Spanish, by only notifying about 20 neighbors of the SEPA review, by posting signs in a corn field, by not providing informational paperwork, by refusing to answer questions about the project, and by failure to attend a public meeting regarding the digester on November 30, 2023.

The City of Sunnyside did not *identify reasonable alternatives,* such as on-farm digesters, a more remote location, limitations on hours for manure transport, different methods of manure management and disposal, or the "no-action" alternative.

WAC 197-11-055
Timing of the SEPA Process

(b) Agencies shall identify the times at which the environmental review shall be conducted either in their procedures or on a case-by-case basis. Agencies may also organize environmental review in phases, as specified in WAC 197-11-060(5).

---

[6] See Monitoring Wells LYV-PS-031, LYV-PS-032, and LYV-PS-033 on Ecology's Environmental Information Monitoring Data Base at https://apps.ecology.wa.gov/eim/search/Groundwater/GWSearchResults.aspx?ResultType=GroundwaterWellTab&StudyUserIds=MRED&StudyUserIdSearchType=Contains&LocationCounties=Yakima&HasGroundwaterData=True

The City of Sunnyside did not state that the environmental review for the Sunnyside RNG project would be organized in phases.

(c) Appropriate consideration of environmental information shall be completed before an agency commits to a particular course of action (WAC 197-11-070).

The Port of Sunnyside committed to the Sunnyside RNG project by proposing the sale of property to Pacific AG in November 2022.[7] The City of Sunnyside issued a determination of non-significance for that sale on December 6, 2022.[8] Sale of real estate for a designated purpose is a commitment to a course of action.

Notice of the sale was not properly advertised. Public comments regarding the sale have not been posted. The City of Sunnyside approved an MDNS for the Sunnyside RNG project on June 22, 2023, six months after sale approval.

*(4) **Applicant review at conceptual stage.** In general, agencies should adopt procedures for environmental review and for preparation of EISs on private proposals at the conceptual stage rather than the final detailed design stage.[9]*

(a) If an agency's only action is a decision on a building permit or other license that requires detailed project plans and specifications, agencies shall provide applicants with the opportunity for environmental review under SEPA prior to requiring applicants to submit such detailed project plans and specifications.

(b) Agencies may specify the amount of detail needed from applicants for such early environmental review, consistent with WAC 197-11-100 and 197-11-335, in their SEPA or permit procedures.

(c) This subsection does not preclude agencies or applicants from preliminary discussions or exploration of ideas and options prior to commencing formal environmental review.

On November 30, 2023, Harrison Pettit from Pacific AG told attendees at a public meeting regarding the Sunnyside RNG project that conversations regarding the project have been ongoing for two years. The fact that the Port of Sunnyside sold property to Pacific Ag for the project indicates a commitment on the part of the Port of Sunnyside and the City of Sunnyside to the biodigester project.

There is no documentation of alternatives as addressed in RCW 43.21C.030(2)(c)(iii), RCW 43.21C.030(2)(e), WAC 197-11-030(2), WAC 197-11-060 (1), WAC 197-11-060

---

[7] Port of Sunnyside Property Sale.
http://www.friendsoftoppenishcreek.org/cabinet/data/AVS%203%20SS%20RNG%20Property%20Sale%20Notice.pdf

[8] DNS for Property Sale.
http://www.friendsoftoppenishcreek.org/cabinet/data/SS%20RNG%20DNS_SEPA-2022.0046.pdf

[9] FOTC assumed in July of 2023 that the Sunnyside RNG project is a public and private partnership, based on statements in the June 22, 2023, MDNS. However, at a November 30, 2023 public meeting regarding the project, Harrison Pettit from Pacific Ag stated several times that this is a private project.

(2), WAC 197-11-060 (3), WAC 197-11-080(1), WAC 197-11-400 (2), WAC 197-11-402(1), WAC 197-11-402(9), WAC 197-11-408(2), WAC 197-11-440(4), WAC 197-11-440(5), WAC 197-11-655(3). According to WAC 197-11-440(5)(b)(ii) *The "no-action" alternative shall be evaluated and compared to other alternatives.*

(5) An overall decision to proceed with a course of action may involve a series of actions or decisions by one or more agencies. If several agencies have jurisdiction over a proposal, they should coordinate their SEPA processes wherever possible. The agencies shall comply with lead agency determination requirements in WAC 197-11-050 and 197-11-922.

(6) To meet the requirement to insure that environmental values and amenities are given appropriate consideration along with economic and technical considerations, environmental documents and analyses shall be circulated and reviewed with other planning documents to the fullest extent possible.

Selected environmental documents for the Sunnyside RNG project were first shared with the public on May 23, 2023. A Traffic Impact Analysis was not published until July of 2023. There is still no approved air study. Questions regarding increased pollution related to the production of manure to feed the digester, and emissions from the digestate produced by the digester have not been answered.

WAC 197-11-060 (4) Impacts.

(a) SEPA's procedural provisions require the consideration of "environmental" impacts (see definition of "environment" in WAC 197-11-740 and of "impacts" in WAC 197-11-752), with attention to impacts that are likely, not merely speculative. (See definition of "probable" in WAC 197-11-782 and 197-11-080 on incomplete or unavailable information.)

(b) In assessing the significance of an impact, a lead agency shall not limit its consideration of a proposal's impacts only to those aspects within its jurisdiction, including local or state boundaries (see WAC 197-11-330(3) also).

(c) Agencies shall carefully consider the range of probable impacts, including short-term and long-term effects. Impacts shall include those that are likely to arise or exist over the lifetime of a proposal or, depending on the particular proposal, longer.

(d) A proposal's effects include direct and indirect impacts caused by a proposal. Impacts include those effects resulting from growth caused by a proposal, as well as the likelihood that the present proposal will serve as a precedent for future actions. For example, adoption of a zoning ordinance will encourage or tend to cause particular types of projects or extension of sewer lines would tend to encourage development in previously unsewered areas.

(e) The range of impacts to be analyzed in an EIS (direct, indirect, and cumulative impacts, WAC 197-11-792) may be wider than the impacts for which mitigation measures are required of applicants (WAC 197-11-660). This will depend upon the specific impacts, the extent to which the adverse impacts are attributable to the applicant's proposal, and the capability of applicants or agencies to control the impacts in each situation.

This is a large project. This bio-digester may be one of the largest in the United States. Impacts will extend beyond the Sunnyside City Limits.

- There will be increased traffic on Yakima County roads to haul manure and crop residues to the digester, to haul digestate from the digester, to haul composted digestate to markets. Increased traffic brings increased pollution of the air with nitrogen oxides and particulate matter. Increased traffic brings increased wear and tear on county roads and costs to tax payers across the county. FOTC submitted an evaluation of the Sunnyside RNG TIA to Yakima County and the Port of Sunnyside on August 28, 2023.[10] We await responses.
- If dairies receive up to $200 per year per cow for manure, there is an incentive to increase the number of cows in each herd. More cows mean increased leaching to the aquifers, and increased air emissions. More cows mean more land taken out of production of fruits and vegetables and more land devoted to dairies and cattle feed. Corn and alfalfa, the major crops for cattle feed, require large amounts of water. Corn is hard on the land, requires large amounts of fertilizer and introduces a wide range of plant pathogens.
- FOTC does not believe it is possible to test for and screen out all the possible contaminants in digestate. There is a significant risk of spreading pathogens to a large number of farming operations when digestate is spread as fertilizer or used as animal bedding. For example, cryptosporidium is a common and wide spread zoonotic parasite that attacks young calves and is more common on dairies with intense confinement and moist conditions.[11] If there is cryptosporidium in manure used as feedstock, the parasite may proliferate in the digesters, live in the digestate, and infect soils for miles around where farmers spread digestate. Cryptosporidium could infect large numbers of animals housed in facilities that use the digestate for bedding.
- If dairies receive up to $200 per year per cow for manure, the up to 25 LYV dairies that participate in this project have a serious economic advantage over the 15 or more dairies that do not. If a dairy has 1,000 milk cows and receives $200 per year per cow, that dairy will increase annual income by $200,000. This makes a difference in which dairies survive and which do not.
- Sunnyside RNG has not described contracts with dairies. FOTC believes there is a potential for this project to squeeze out non-participating dairies and to create dairy dependence on the digester for economic survival. If dependence occurs, then LYV dairies are at the mercy of digester operators who can raise or lower the rates of payment for manure. There is a troubled dairy digester in Iowa where

---

[10] See Attachment 4

[11] Oregon State University. The cryptosporidium parasite and its effect on calves and humans. https://extension.oregonstate.edu/animals-livestock/beef/cryptosporidium-parasite-its-effect-calves-humans *Cryptosporidium is* most infectious when the parasite is passed in feces and then ingested. Infected calves can have crypto in their feces for weeks after they are no longer sick.
Crypto eggs have a tough outer shell and are resistant to disinfectants, even chlorine bleach. They can survive outside the body and in the environment for long periods. The eggs can be killed by generous applications of a 3% hydrogen peroxide solution as well as exposure to high temperatures in excess of 160° F, which is hotter than most domestic tap water.

economic benefits do not pencil out. A recent newspaper article[12] about the Waunakee Digester in Wisconsin stated:

Many of the assumptions the company made at the start were wrong. In the future, the business model will have to be tweaked, and farmers sending manure to comparable operations may need to pay the plant to accept it.

- Regarding global warming: To our knowledge no one has calculated how much diesel fuel would be burned to transport manure and digestate for this project.
- Regarding global warming: Dairies produce at least one metric ton of CO_2 equivalents via enteric fermentation for every metric ton of methane produced in anaerobic manure lagoons. Consider a hypothetical community that produces 0.5 MMT CO_2 equivalents of methane via enteric fermentation, and 0.5 MMT CO_2 equivalents of methane from manure lagoons. This equals 1 MMT CO_2 equivalents of methane total. Suppose the community can process all the methane from manure lagoons into renewable natural gas. The total is now 0.5 MMT CO_2 equivalents of methane. Because the operation is profitable the community doubles the number of cows. All the methane from manure lagoons is captured, but the community now produces 1 MMT CO_2 equivalents of methane from enteric fermentation – back to the starting point. Plus the emission of other air pollutants has doubled & emissions from manure transport has doubled, etc.
- We do not see an accounting of how much income for the proposed digester comes from the Washington Cap and Trade program, and from tax payers. The Cap and Trade program does not last forever. Can the Sunnyside RNG digester continue to profit if subsidies decline?
- According to the EPA AgStar program[13] there are many ways to reduce methane emissions from livestock manure management. Some methods are:
    - *Anaerobic digesters – 50% reduction*
    - *Daily spread – 45% reduction*
    - *Pasture based management – 45% reduction*
    - *Composting – 45% reduction*
    - *Solid storage – 45% reduction*
    - *Manure drying practices – 45% reduction*
    - *Semi-permeable covers – 40% reduction*
    - *Decreased manure storage time – 40% reduction*
    - *Composted bedded pack barns – 30% reduction*
    - *Solid separation of manure solids prior to entry to wet/anaerobic environment – 20% reduction*

  But anaerobic digesters cost so much more than the other methods.

---

[12] State-financed manure digester plagued by spills, explosions. 2015. https://archive.jsonline.com/news/statepolitics/state-financed-manure-digester-plagued-by-spills-explosion-b99435123z1-290263421.html

[13] EPA AgStar. (2023) Practices to Reduce Methane Emissions from Livestock Manure Management. https://www.epa.gov/agstar/practices-reduce-methane-emissions-livestock-manure-management

- The Sunnyside RNG New Source Review (NSR) application requires more information and does not quantify the amount of air pollutants currently in the LYV ambient air. It does not estimate the percentage of air pollution attributable to the proposed Sunnyside RNG digester if it becomes reality. Would Sunnyside residents be forced to stop using wood stoves to compensate for digester emissions to keep Yakima County in compliance with U.S. criteria air standards?
- There are significant increases in morbidity and mortality associated with fine particulate air pollution.[14] One study found a decrease of 10 $\mu g/m^3$ of fine particulate concentration was associated with an estimated increase in life expectancy equal to 0.77 years.[15] By how much would fine particulate matter levels increase in the LYV if the Sunnyside RNG digester were built? What is the cost of human health and life?

WAC 197-11-060 Content of Environmental Review

*(5) **Phased review.***

(a) Lead agencies shall determine the appropriate scope and level of detail of environmental review to coincide with meaningful points in their planning and decision-making processes. (See WAC 197-11-055 on timing of environmental review.)

(b) Environmental review may be phased. If used, phased review assists agencies and the public to focus on issues that are ready for decision and exclude from consideration issues already decided or not yet ready. Broader environmental documents may be followed by narrower documents, for example, that incorporate prior general

[15] Pope CA 3rd, Ezzati M, Dockery DW. Fine-particulate air pollution and life expectancy in the United States. N Engl J Med. 2009 Jan 22;360(4):376-86. doi: 10.1056/NEJMsa0805646. PMID: 19164188; PMCID: PMC3382057. https://www.ncbi.nlm.nih.gov/pmc/articles/PMC3382057/

discussion by reference and concentrate solely on the issues specific to that phase of the proposal.

(c) Phased review is appropriate when:

(i) The sequence is from a nonproject document to a document of narrower scope such as a site specific analysis (see, for example, WAC 197-11-443); or

(ii) The sequence is from an environmental document on a specific proposal at an early stage (such as need and site selection) to a subsequent environmental document at a later stage (such as sensitive design impacts).

(d) Phased review is not appropriate when:

(i) The sequence is from a narrow project document to a broad policy document;

(ii) It would merely divide a larger system into exempted fragments or avoid discussion of cumulative impacts; or

(iii) It would segment and avoid present consideration of proposals and their impacts that are required to be evaluated in a single environmental document under WAC 197-11-060 (3)(b) or 197-11-305(1); however, the level of detail and type of environmental review may vary with the nature and timing of proposals and their component parts.

(e) When a lead agency knows it is using phased review, it shall so state in its environmental document.

(f) Agencies shall use the environmental checklist, scoping process, nonproject EISs, incorporation by reference, adoption, and supplemental EISs, and addenda, as appropriate, to avoid duplication and excess paperwork.

(g) Where proposals are related to a large existing or planned network, such as highways, streets, pipelines, or utility lines or systems, the lead agency may analyze in detail the overall network as the present proposal or may select some of the future elements for present detailed consideration. Any phased review shall be logical in relation to the design of the overall system or network, and shall be consistent with this section and WAC 197-11-070.

The City of Sunnyside did not state that the city would use a phased review. FOTC believes the City of Sunnyside should have gathered information sooner and presented all relevant environmental information with the initial SEPA review. Because the process now involves addressing a SEPA Review and then addressing Addenda to the SEPA review, the amount of study and paperwork has doubled, at least for FOTC.

WAC 197-11-080

Incomplete or unavailable information.

(1) If information on significant adverse impacts essential to a reasoned choice among alternatives is not known, and the costs of obtaining it are not exorbitant, agencies shall obtain and include the information in their environmental documents.

(2) When there are gaps in relevant information or scientific uncertainty concerning significant impacts, agencies shall make clear that such information is lacking or that substantial uncertainty exists.

(3) Agencies may proceed in the absence of vital information as follows:

(a) If information relevant to adverse impacts is essential to a reasoned choice among alternatives, but is not known, and the costs of obtaining it are exorbitant; or

(b) If information relevant to adverse impacts is important to the decision and the means to obtain it are speculative or not known;

Then the agency shall weigh the need for the action with the severity of possible adverse impacts which would occur if the agency were to decide to proceed in the face of uncertainty. If the agency proceeds, it shall generally indicate in the appropriate environmental documents its worst case analysis and the likelihood of occurrence, to the extent this information can reasonably be developed.

(4) Agencies may rely upon applicants to provide information as allowed in WAC 197-11-100.

The City of Sunnyside did not document incomplete information, as required in the rule. FOTC believes that significant information is missing, and this should have been documented. See the concerns described on pages 6 to 9 above. We are especially concerned about costs to tax payers, impact on non-participating dairies and other farms, spreading disease, unknown increases in LYV air pollution, wear and tear on county roads, increases in traffic accidents, dangers to school children, and risks of fire and explosions.

Although the chances of fires and explosions are not great, damage when such incidents occur may be high and could include death.[16] A quality SEPA review must acknowledge this risk and address it. See WAC 197-11-794 (2).

The Sunnyside RNG SEPA Check list says:

Anaerobic-digestor-based renewable natural gas facilities produce biogas composed of methane (CH4) which is a flammable gas (under limited circumstances), hydrogen sulfide (H2S) which is both a flammable and toxic gas, along with CO2 and vocs. These components will be contained in anaerobic tanks with membrane roofs and in the downstream raw biogas piping systems designed in compliance with industry standards for sour gas facilities.

Methane (CH4) and Hydrogen Sulfide (H2S) are products of the anaerobic digestion process and both are considered hazardous with H2S also considered toxic. Both components will be present in the facility tanks and piping. Their hazardous and/or toxic characteristics along with response measures, should either be released to the atmosphere, can be found in Safety Data Sheets (SDS). Process chemicals such as solvents, oils, lubricants, antifreeze, ferric chloride and natural gas injection calibration gases such as Nitrogen, Propane, Helium, and potentially odorant will be used in limited quantities.

Standard emergency and fire services, as well as potentially confined space rescue. Other special health and safety planning is underway and will be confirmed with emergency

[16] See Attachment 2

services and County Health Department. Standard emergency services equipment includes self-contained breathing apparatus (SCBA) appropriate for potential exposure.

The following measures may be implemented to reduce or control environmental health hazards: A health and safety plan would be followed during construction to address worker safety and to minimize exposure to potential environmental health hazards. To help detect potential leaks quickly, an odorant may be added to the gas . Pressure and flow at the facilities will be monitored to ensure proper operation and reduce potential risk for fire and explosion. The centralized gas cleaning unit would be designed with internal shutoff valves that will switch automatically if the system detects a malfunction. The centralized gas cleaning unit would be outfitted with control technology to ensure that emissions are below the acceptable source impact level for air pollutants associated with project operation. The extremely limited areas where toxic/ hazardous materials are utilized will have impermeable surfaces and curbing to contain any potential spills.

Every methane producing facility with spills, leaks, fires, and explosions said the same things when they convinced communities to permit operations. Nothing in this statement is enforceable.[17]

The checklist says, *The following measures may be implemented to reduce or control environmental health hazards.*

If there is an accident and victims argue for compensation, Sunnyside RNG insurance companies can simply say, 'W never promised to do those things. We said those measures *may be implemented.*'

A useful SEPA check list would tell the reader, among other things:

- Where on the facility would alarms and monitors be located?
- What would be the pressure and flow danger signs?
- Would monitoring be automated or by trained personnel?
- What would the alarms detect?
- Frequency of alarm checks to make sure they function properly?
- How would the facility check for corrosion in the piping system, in the tank floors and walls?
- How often would piping be checked for leaks?
- When would equipment be replaced as the facility ages?
- Required safety training for staff – content, how often?
- Evacuation routes?
- What are protocols for rescuing trapped and endangered workers?
- Would there be monitoring for release of pathogens in effluent and air?
- Would there be fenceline monitoring?

---

[17] The City of Sunnyside Municipal Code 18.04.120.E.3 states: *The applicant's proposed mitigation measures must be in writing and must be specific. For example, proposals to "control noise" or "prevent storm water runoff" are inadequate, whereas proposals to "muffle machinery to X decibels" or "construction 200-foot storm water retention pond at Y location" are adequate.*

- What are proposed protocols for notifying neighbors of leaks and dangers?
- Describe a worst case scenario for fires and explosions

WAC 197-11-158 SEPA/GMA project review—Reliance on existing plans, laws, and regulations.

(1) In reviewing the environmental impacts of a project and making a threshold determination, a GMA county/city may, at its option, determine that the requirements for environmental analysis, protection, and mitigation measures in the GMA county/city's development regulations and comprehensive plan adopted under chapter 36.70A RCW, and in other applicable local, state, or federal laws or rules, provide adequate analysis of and mitigation for some or all of the specific adverse environmental impacts of the project.

(2) In making the determination under subsection (1) of this section, the GMA county/city shall:

(d) Place the following statement in the threshold determination if all of a project's impacts are addressed by other applicable laws and no conditions will be required under SEPA: "The lead agency has determined that the requirements for environmental analysis, protection, and mitigation measures have been adequately addressed in the development regulations and comprehensive plan adopted under chapter 36.70A RCW, and in other applicable local, state, or federal laws or rules, as provided by RCW 43.21C.240 and WAC 197-11-158. Our agency will not require any additional mitigation measures under SEPA."

The City of Sunnyside did not select this option.

WAC 197-11-164 Planned actions—Definition and criteria.

(1) Under RCW 43.21C.440, GMA counties/cities may designate a planned action.

FOTC interpretation is that the Sunnyside RNG project is not a planned action.

WAC 197-11-330 Threshold determination process.

(3) In determining an impact's significance (WAC 197-11-794), the responsible official shall take into account the following, that:

(a) The same proposal may have a significant adverse impact in one location but not in another location;

(b) The absolute quantitative effects of a proposal are also important, and may result in a significant adverse impact regardless of the nature of the existing environment;

(c) Several marginal impacts when considered together may result in a significant adverse impact;

(d) For some proposals, it may be impossible to forecast the environmental impacts with precision, often because some variables cannot be predicted or values cannot be quantified.

(e) A proposal may to a significant degree:

(i) Adversely affect environmentally sensitive or special areas, such as loss or destruction of historic, scientific, and cultural resources, parks, prime farmlands, wetlands, wild and scenic rivers, or wilderness;

(ii) Adversely affect endangered or threatened species or their habitat;

(iii) Conflict with local, state, or federal laws or requirements for the protection of the environment; and

(iv) Establish a precedent for future actions with significant effects, involves unique and unknown risks to the environment, or may affect public health or safety.

*(4) If after following WAC **197-11-080** and **197-11-335** the lead agency reasonably believes that a proposal may have a significant adverse impact, an EIS is required.*

(5) A threshold determination shall not balance whether the beneficial aspects of a proposal outweigh its adverse impacts, but rather, shall consider whether a proposal has any probable significant adverse environmental impacts under the rules stated in this section. For example, proposals designed to improve the environment, such as sewage treatment plants or pollution control requirements, may also have significant adverse environmental impacts.

Many people believe that the SS RNG digester should be located away from the City of Sunnyside, in a more remote area.

People note that the proposed digester will be situated near the Windmill Mushroom Farms that already sends odorous emissions into the ambient air, and the Nutrien Fertilizer Plant with a history of a fire that required evacuation of neighbors, and the Sunnyside wastewater treatment plant that sprays odorous effluent onto nearby fields.

The proposed digester would be near the area where the poorer people of Sunnyside live and farther from more affluent areas. A previous site, near more affluent areas, and near the Williams natural gas pipeline, was rejected. No one is stating the reason.

Soil at this site, Quincy loamy fine sand, is "excessively drained" according to the Natural Resources Conservation Service. Nearby monitoring wells at the Port of Sunnyside show high levels of nitrates in the underlying aquifer. Sunnyside RNG has not stated what kind of liner will be used for digester lagoons. It is reasonable to expect that spills on the digester site would quickly leach to the aquifer.

Approval of this project without an Environmental Impact Statement would demonstrate to the public that Washington laws to protect people in marginalized neighborhoods mean nothing.

197-11-335 Additional information.

The lead agency shall make its threshold determination based upon information reasonably sufficient to evaluate the environmental impact of a proposal (WAC 197-11-055(2) and 197-11-060(3)). The lead agency may take one or more of the following actions if, after reviewing the checklist, the agency concludes that there is insufficient information to make its threshold determination:

(1) Require an applicant to submit more information on subjects in the checklist;

(2) Make its own further study, including physical investigations on a proposed site;

(3) Consult with other agencies, requesting information on the proposal's potential impacts which lie within the other agencies' jurisdiction or expertise (agencies shall respond in accordance with WAC 197-11-550); or

(4) Decide that all or part of the action or its impacts are not sufficiently definite to allow environmental analysis and commit to timely, subsequent environmental analysis, consistent with WAC 197-11-055 through 197-11-070.

There is insufficient information in the Sunnyside RNG checklist to evaluate the environmental impact of the proposed digester.

- Only vague speculation about project expansion
- A Geotechnical Report and Phase I ESA are referenced but not available for review
- There is no air permit. The application posted on the City of Sunnyside web site that appears to have been accepted by the Yakima Regional Clean Air Agency was not in fact accepted. The YRCAA returned it to Sunnyside RNG for more information
- Could the answers be any vaguer? How about this: "Best management practices will be used to reduce and control erosion. Local and state laws will be followed. Silt fence, construction entrance, an inlet protection are planned."[18]
- The Environmental Checklist assures the public that emissions from the proposed digester will not exceed:
    - CO - 100 tons per year (tpy)
    - NOX - 40 tons per year (tpy)
    - SO2 - 40 tons per year (tpy)
    - PM - 25 tons per year (tpy)
    - PM10-15tpy
    - PM25 -10 tpy

[18] The City of Sunnyside Municipal Code 18.04.120.E.3 states: *The applicant's proposed mitigation measures must be in writing and must be specific. For example, proposals to "control noise" or "prevent storm water runoff" are inadequate, whereas proposals to "muffle machinery to X decibels" or "construction 200-foot storm water retention pond at Y location" are adequate.*

Suppose the SS RNG digester only emits 5 tons per year of PM 2.5, fine particulate matter, and Windmill Mushroom Farms only emits 5 tons per year of fine particulate matter, and Nutrien Solutions only emits 5 tons per year of fine particulate matter, and the City of Sunnyside Waste Water Treatment Plant only emits 5 tons per year of fine particulate matter. The Total is 20 tons per year. What does this mean for South Sunnyside air quality? Wouldn't it be better to study this problem before ground is broken, rather than trying to protect human health with home air filters and breathing treatments afterwards?

- *Stormwater runoff will be retained on site and infiltrated into the ground at various locations including a potential stormwater pond. This water will not flow into other waters.* This means that stormwater will wash spilled manure and digestate from the site into the ground. Who will monitor for onsite spills? Is groundwater monitoring appropriate here?
- *Natural gas used for heat (the boilers) is accounted for in the air emissions as well as avoided methane calculations.* This natural gas should not be counted in avoided methane calculations.
- *Thermal energy will be recaptured from the amine re boiler for heating other site processes. Where appropriate variable rate pumps will be used.* There is insufficient information to quantify these proposed savings. There is insufficient information for the average reader, including City of Sunnyside Officials, to understand the nature of an amine boiler.
- *To help detect potential leaks quickly, an odorant may be added to the gas.* An odorant "may" be added. You "may" win the lottery
- *Noise is not anticipated to be a problem.* Please tell us why not.
- FOTC's table top calculation, using data from the SS RNG Traffic Impact Analysis estimates there will be an additional 1,500 miles of truck traffic per day mostly on Yakima County Roads. Heavy duty trucks inflict about 2,500 times more wear and tear on roads than private cars. There is no estimate of cost to maintain the impacted county roads.

WAC 197-11-340 Determination of nonsignificance (DNS).

(2)(c) Any person, affected tribe, or agency may submit comments to the lead agency within fourteen days of the date of issuance of the DNS.
(2)(f) The responsible official shall reconsider the DNS based on timely comments and may retain or modify the DNS or, if the responsible official determines that significant adverse impacts are likely, withdraw the DNS or supporting documents. When a DNS is modified, the lead agency shall send the modified DNS to agencies with jurisdiction.
(3)(a) The lead agency shall withdraw a DNS if:

(i) There are substantial changes to a proposal so that the proposal is likely to have significant adverse environmental impacts;

(ii) There is significant new information indicating, or on, a proposal's probable significant adverse environmental impacts; or

(iii) The DNS was procured by misrepresentation or lack of material disclosure; if such DNS resulted from the actions of an applicant, any subsequent environmental

checklist on the proposal shall be prepared directly by the lead agency or its consultant at the expense of the applicant.

(b) Subsection (3)(a)(ii) shall not apply when a nonexempt license has been issued on a private project.

(c) If the lead agency withdraws a DNS, the agency shall make a new threshold determination and notify other agencies with jurisdiction of the withdrawal and new threshold determination. If a DS is issued, each agency with jurisdiction shall commence action to suspend, modify, or revoke any approvals until the necessary environmental review has occurred (see also WAC 197-11-070).

The City of Sunnyside issued a mitigated determination of non-significance (MDNS) of the SS RNG project on June 22, 2023.

The Friends of Toppenish Creek submitted an appeal of the MDNS on July 6, 2023.[19]

There is no evidence that the responsible official reconsidered the MDNS based on FOTC's lengthy comments, as required by WAC 197-11-340(2)(f).

FOTC maintains there was a lack of material disclosure due to the absence of data regarding air quality, risks for fires and explosion, and traffic impacts. The agency with expertise for air, the YRCAA, did not comment. A Traffic Impact Analysis (TIA) was not available for review prior to our July 6, 2023 appeal.

WAC 197-11-350 Mitigated DNS.

The purpose of this section is to allow clarifications or changes to a proposal prior to making the threshold determination.

(1) In making threshold determinations, an agency may consider mitigation measures that the agency or applicant will implement.

(2) After submission of an environmental checklist and prior to the lead agency's threshold determination on a proposal, an applicant may ask the lead agency to indicate whether it is considering a DS. If the lead agency indicates a DS is likely, the applicant may clarify or change features of the proposal to mitigate the impacts which led the agency to consider a DS likely. The applicant shall revise the environmental checklist as may be necessary to describe the clarifications or changes. The lead agency shall make its threshold determination based upon the changed or clarified proposal. If a proposal continues to have a probable significant adverse environmental impact, even with mitigation measures, an EIS shall be prepared.

(3) Whether or not an applicant requests early notice under subsection (2), if the lead agency specifies mitigation measures on an applicant's proposal that would allow it to issue a DNS, and the proposal is clarified, changed, or conditioned to include those measures, the lead agency shall issue a DNS.

---

[19] See Attachment 2

(4) Environmental documents need not be revised and resubmitted if the clarifications or changes are stated in writing in documents that are attachments to, or incorporate by reference, the documents previously submitted. An addendum may be used, see Part Six.

The June 22, 2023 MDNS for the SS RNG project stated the following mitigation measures:

Mitigation Measure: An Inadvertent Discovery Plan shall be created and submitted to the City of Sunnyside as part of the building permit package for the prosed development.

Mitigating Measures: a stormwater management plan is required to be submitted for review and approval by City of Sunnyside public works department prior to construction. The plan must meet the following design standards:

a) Stormwater retention or detention shall be provided. A professional engineer registered in the state of Washington shall design all drainage facilities and components. Drainage plans using best management practices and design requirements must be submitted to and approved by City of Sunnyside prior to grading or development.
b) Post development stormwater flow rates and volumes shall not exceed predevelopment conditions. The standard of full retention of the 25-year storm event generally meets the goal.
c) The depth to groundwater should be determined prior to planning the layout of stormwater facilities. If a stormwater infiltration facility will be used for the disposal of runoff, a permeability test should be conducted initially at the site to determine existing infiltration rates prior to the design stage.

Mitigation Measure: Dust a. A dust control plan must be filed with the Yakima Regional Clean Air Authority.

Documentation for most of these mitigation measures is still missing, namely there is no:

- Inadvertent Discovery Plan, although the addendum letter from SS RNG claims one exists
- NPDES Construction Stormwater permit, although the addendum letter from SS RNG claims one exists
- Stormwater Pollution Prevention Plan, although the addendum letter from SS RNG claims one exists
- Consultation with the WA State Dept. of Ecology and the Yakima Health District regarding a Notice of Intent to operate under terms and conditions of a solid waste permit
- Depth to groundwater and permeability tests

On December 4, 2023, FOTC submitted a public records request to Yakima County Emergency Services for information re conversations with Sunnyside RNG regarding possible fires and explosions. On December 5, 2023, Yakima County Emergency

Services informed FOTC that they have no records of conversations with Pacific Ag/Sunnyside RNG regarding the proposed manure bio-digester.

FOTC interprets this to mean that project proponents have not adequately prepared for possible fires and explosions at the site. There is abundant information demonstrating the possibility of fires and explosions related to methane production facilities.

WAC 197-11-355 Optional DNS process.

In the City of Sunnyside's May 23, 2023 Notice of Environmental Review the city stated:

NOTICE OF ENVIRONMENTAL REVIEW This is to notify agencies with jurisdiction and environmental expertise and the public that the City of Sunnyside, Planning Division, has been established as the lead agency, under WAC § 197-11-928 for this project. The City of Sunnyside has reviewed the proposed project for probable adverse environmental impacts and expects to issue a Determination of Nonsignificance (DNS) per WAC § 197-11-355. The proposal may include mitigation measures under applicable codes and the project review process may incorporate or require mitigation measures regardless of whether an EIS is prepared. A copy of the subsequent threshold determination may be obtained by request and may be appealed pursuant to SMC Ch. 18.04.

However the City of Sunnyside has not incorporated WAC 197-11-355 by reference. See City of Sunnyside Municipal Code, Chapter 18.04 available at https://www.codepublishing.com/WA/Sunnyside/#!/Sunnyside18/Sunnyside1804.html#18.04.020

18.04.080 Categorical exemptions and threshold determinations, provisions adopted by reference.

Regarding the rules for deciding whether a proposal has a "probable significant adverse environmental impact" requiring an EIS to be prepared, and the rules for evaluating the impacts of proposals not requiring an EIS, the City adopts the following sections of Chapter 197-11 WAC by reference:

WAC

197-11-300 Purpose
197-11-305 Categorical Exemptions
197-11-310 Threshold Determination Required
197-11-315 Environmental Checklist
197-11-330 Threshold Determination Process
197-11-335 Additional Information
197-11-340 Determination of Non-Significance

197-11-350 Mitigated Determinations of Non-Significance
197-11-360 Determinations of Significance/Initiation of Scoping
197-11-390 Effects of Threshold Determination
[Ord. 1475 § 2, 1984.]

FOTC questions whether the city can invoke a rule that the city has not approved. The city did not respond when FOTC brought this fact to the city's attention.

WAC 197-11-400 Purpose of EIS.

(1) The primary purpose of an environmental impact statement is to ensure that SEPA's policies are an integral part of the ongoing programs and actions of state and local government.

(2) An EIS shall provide impartial discussion of significant environmental impacts and shall inform decision makers and the public of reasonable alternatives, including mitigation measures, that would avoid or minimize adverse impacts or enhance environmental quality.

(3) Environmental impact statements shall be concise, clear, and to the point, and shall be supported by the necessary environmental analysis. The purpose of an EIS is best served by short documents containing summaries of, or reference to, technical data and by avoiding excessively detailed and overly technical information. The volume of an EIS does not bear on its adequacy. Larger documents may even hinder the decision making process.

(4) The EIS process enables government agencies and interested citizens to review and comment on proposed government actions, including government approval of private projects and their environmental effects. This process is intended to assist the agencies and applicants to improve their plans and decisions, and to encourage the resolution of potential concerns or problems prior to issuing a final statement. An environmental impact statement is more than a disclosure document. It shall be used by agency officials in conjunction with other relevant materials and considerations to plan actions and make decisions.

An Environmental Impact Statement, as described in WAC 197-11-400 is essential for quality decision making. A project as large as the Sunnyside RNG digester should not proceed without study of environmental information at this level

WAC 197-11-500 Purpose of this part.

This part provides rules for:

(1) Notice and public availability of environmental documents, especially environmental impact statements;

(2) Consultation and comment by agencies and members of the public on environmental documents;

(3) Public hearings and meetings; and

(4) Lead agency response to comments and preparation of final environmental impact statements. Review, comment, and responsiveness to comments on a draft EIS are the focal point of the act's commenting process because the DEIS is developed as a result of scoping and serves as the basis for the final statement.

This section especially addresses public notice for Environmental Impact Statements, but it is not limited to EIS. FOTC believes that this section also addresses Environmental Review in sections that do not limit discussion to EIS.

WAC 197-11-502 Inviting comment.

(1) Agency efforts to involve other agencies and the public in the SEPA process should be commensurate with the type and scope of the environmental document.

(2) Consulted agencies have a responsibility to respond in a timely and specific manner to requests for comments (WAC 197-11-545, 197-11-550, and 197-11-724).

The Yakima Regional Clean Air Agency, the agency tasked with enforcing the Clean Air Act in Yakima County, did not respond to the City of Sunnyside's request for comments on the May 2023 Notice of Environmental Review. Consequently the MDNS did not contain sufficient analysis of related air impacts. If there were an adequate analysis of air impacts the City of Sunnyside might have issued a Determination of Significance that would have changed the course of these actions.

*(3) **Threshold determinations.***

(a) Agencies shall send DNSs to other agencies with jurisdiction, if any, as required by WAC 197-11-340(2) and 197-11-355.

The City of Sunnyside has never incorporated WAC 197-11-355 by reference.

(b) For DNSs issued under WAC 197-11-340(2), agencies shall provide public notice under WAC 197-11-510 and receive comments on the DNS for fourteen days.

The City of Sunnyside provided public notice of the MDNS on June 22, 2023, and stated

Appeal Period: This MDNS is issued under WAC 197-11-340(2). The Lead Agency will not act on this proposal for 14 days from the date of issuance. Appeals may be submitted on this proposal to the address below.

However the May 2023 Notice of Environmental Review stated

The City of Sunnyside has reviewed the proposed project for probable adverse environmental impacts and expects to issue a Determination of Nonsignificance (DNS) per WAC § 197-11-355.

FOTC did appeal the MDNS on July 6, 2023. The City of Sunnyside scheduled a hearing date for August 23, 2023. The City of Sunnyside cancelled the hearing on August 16, 2023. The city did not put the cancellation in an official document, but relied instead on an email that said:

After consultation with the City's legal team, it has been discovered that the Mitigated Determination of Nonsignificance (MDNS) issued on June 22, 2023, cannot at this time be appealed. The reason the MDNS cannot be appeal is because the MDNS only serves as an advisory statement on behalf of the City. In order to process an appeal, the MDNS is required to be tied to a development permits, such as a land use review, engineering permit, or building permit. None of those items have been issued for the site at this time, therefore the City cannot process a standalone MDNS appeal. See - Ellensburg Cement Products, Inc. v. Kittitas County, 179 Wn.2d 737 (2014).

FOTC disputed the cancellation to no avail. The City of Sunnyside did not cite rules that allow an unelected official to cancel a legally authorized hearing. In fact, the city did not point to any places in WAC 197-11 that might support the cancellation. It is inappropriate for the city to cite case law as though issuing a ruling from the bench.

FOTC disagrees with the statement *the MDNS only serves as an advisory statement on behalf of the City.* FOTC contends that environmental review means *Deciding whether a proposal has a probable significant adverse impact and thus requires an EIS (the threshold determination)* WAC 197-11-300(2)

*(6) **Public hearings and meetings.***

*(a) Public hearings or meetings may be held (WAC **197-11-535**). Notice of such public hearings shall be given under WAC **197-11-510** and may be combined with other agency notice.*

*(b) In conjunction with the requirements of WAC **197-11-510**, notice of public hearings shall be published no later than ten days before the hearing. For nonproject proposals, notice of the public hearing shall be published in a newspaper of general circulation in the general area where the lead agency has its principal offices. For nonproject proposals having a regional or statewide applicability, copies of the notice shall be given to the Olympia bureaus of the Associated Press and United Press International.*

The City of Sunnyside refused to conduct public hearings on this project. As noted, the city cancelled a public hearing of the FOTC appeal. There was no opportunity for the community to learn about risks and benefits related to the SS RNG bio-digester, thus a thwarting of the intent of the law.

WAC 197-11-510 Public notice.

(1) When these rules require notice to be given under this section, the lead agency must use reasonable methods to inform the public and other agencies that an

environmental document is being prepared or is available and that public hearing(s), if any, will be held. The agency may use its existing notice procedures.

Examples of reasonable methods to inform the public are:

(a) Posting the property, for site-specific proposals;

(b) Publishing notice in a newspaper of general circulation in the county, city, or general area where the proposal is located;

(c) Notifying public or private groups with known interest in a certain proposal or in the type of proposal being considered;

(d) Notifying the news media;

(e) Placing notices in appropriate regional, neighborhood, ethnic, or trade journals;

(f) Publishing notice in agency newsletters and/or sending notice to agency mailing lists (either general lists or lists for specific proposals or subject areas); and/or

(g) Mailing or emailing notice to any person, group or agency who has requested notice.

(2) Each agency shall specify its method of public notice in its SEPA procedures, WAC 197-11-904 and 197-11-906. If an agency does not specify its method of public notice or does not adopt SEPA procedures, the agency shall use methods (a) and (b) in subsection (1).

(3) Documents which are required to be sent to the department of ecology under these rules will be published in the SEPA register, which will also constitute a form of public notice. However, publication in the SEPA register shall not, in itself, meet compliance with this section.

FOTC only became aware of the SS RNG MDNS as a result of a public records request. FOTC paid particular attention to public notices in the Yakima Herald Republic because we heard rumors about the proposed digester. We found zero notices in the Yakima Herald Republic or in the Spanish media.

To the best of our knowledge notices were sent to about twenty residences near the proposed site. Many of the recipients only speak Spanish, yet the notices were only in English. This project, if completed will have long lasting impacts on the entire county, yet most people in the county are still unaware.

The City of Sunnyside or the Port of Sunnyside placed a sign in a cornfield at the proposed site next to a highway with a 55 mph speed limit. Public notice was minimal and inadequate.

WAC 197-11-535 Public hearings and meetings.

(1) If a public hearing on the proposal is held under some other requirement of law, such hearing shall be open to consideration of the environmental impact of the proposal, together with any environmental document that is available. This does not require extension of the comment periods for environmental documents.

(2) In all other cases a public hearing on the environmental impact of a proposal shall be held whenever one or more of the following situations occur:

(a) The lead agency determines, in its sole discretion, that a public hearing would assist it in meeting its responsibility to implement the purposes and policies of SEPA and these rules; or

(b) When fifty or more persons residing within the jurisdiction of the lead agency, or who would be adversely affected by the environmental impact of the proposal, make written request to the lead agency within thirty days of issuance of the draft EIS; or

(c) When two or more agencies with jurisdiction over a proposal make written request to the lead agency within thirty days of the issuance of the draft EIS.

(3) Whenever a public hearing is held under subsection (2) of this section, it shall occur no earlier than fifteen days from the date the draft EIS is issued, nor later than fifty days from its issuance. Notice shall be given under WAC 197-11-502(6) and 197-11-510 and may be combined with other agency notice.

(4) If a public hearing is required under this chapter, it shall be open to discussion of all environmental documents and any written comments that have been received by the lead agency prior to the hearing. A copy of the environmental document shall be available at the public hearing.

(5) Comments at public hearings should be as specific as possible (see WAC 197-11-550).

(6) Agencies and their designees may hold informal public meetings or workshops. Such gatherings may be more flexible than public hearings and are not subject to the above notice and similar requirements for public hearings.

(7) Public meetings held by local governments under chapter 36.70B RCW may be used to meet SEPA public hearing requirements as long as the requirements for public hearing in this section are met. A public hearing under this section need not be an open record hearing as defined in RCW 36.70B.020(3).

Based on WAC 197-11-535(2) & (3) FOTC concludes that this section primarily applies to Environmental Impact Statements. However, the City of Sunnyside could have conducted public meetings or workshops to inform residents about the risks and benefits of this proposed project. Such an action would have demonstrated confidence in the intelligence and civic interest of members of the public. Absence of such meetings indicates a propensity to keep the public in the dark.

WAC 197-11-545 Effect of no comment.

*(1) **Consulted agencies.** If a consulted agency does not respond with written comments within the time periods for commenting on environmental documents, the lead agency may assume that the consulted agency has no information relating to the potential impact of the proposal as it relates to the consulted agency's jurisdiction or special expertise. Any consulted agency that fails to submit substantive information to the lead agency in response to a draft EIS is thereafter barred from alleging any defects in the lead agency's compliance with Part Four of these rules.*

*(2) **Other agencies and the public.** Lack of comment by other agencies or members of the public on environmental documents, within the time periods specified by*

these rules, shall be construed as lack of objection to the environmental analysis, if the requirements of WAC 197-11-510 are met.

It is extremely disturbing that the Yakima Regional Clean Air Agency and the Yakima Health District did not comment on the SS RNG Environmental Review. This failure to comment borders on failure to fulfill these agencies' mandated duties.

It is impossible to construct a manure methane bio-digester that produces between 800,000 and 950,000 MMBtu's of renewable natural gas per year without an impact on air quality or human health.

WAC 197-11-600 When to use existing environmental documents.

(1) This section contains criteria for determining whether an environmental document must be used unchanged and describes when existing documents may be used to meet all or part of an agency's responsibilities under SEPA.

(2) An agency may use environmental documents that have previously been prepared in order to evaluate proposed actions, alternatives, or environmental impacts. The proposals may be the same as, or different than, those analyzed in the existing documents.

Pacific Ag/Sunnyside RNG acknowledges that the company must acquire an air quality permit prior to commencing construction. When the YRACC evaluates such an application the YRCAA may incorporate the City of Sunnyside's MDNS, even though the YRCAA failed to comment on air impacts. FOTC would interpret such an action as an attempt to circumvent SEPA laws, and permit a polluting operation.

(3) Any agency acting on the same proposal shall use an environmental document unchanged, except in the following cases:

(a) For DNSs, an agency with jurisdiction is dissatisfied with the DNS, in which case it may assume lead agency status (WAC 197-11-340 (2)(e) and 197-11-948).

(b) For DNSs and EISs, preparation of a new threshold determination or supplemental EIS is required if there are:

(i) Substantial changes to a proposal so that the proposal is likely to have significant adverse environmental impacts (or lack of significant adverse impacts, if a DS is being withdrawn); or

(ii) New information indicating a proposal's probable significant adverse environmental impacts. (This includes discovery of misrepresentation or lack of material disclosure.) A new threshold determination or SEIS is not required if probable significant adverse environmental impacts are covered by the range of alternatives and impacts analyzed in the existing environmental documents.

FOTC has introduced new evidence of potential adverse impacts in the forms of 1. an Evaluation of the Sunnyside RNG Traffic Impact Analysis, 2. Documentation of fires and explosions on other manure bio-digesters, 3. Reference to groundwater issues at the Port of Sunnyside, 4. Data supporting likelihood of cumulative impacts, and 5. Demographic data that demonstrates Environmental Justice concerns.

(c) For EISs, the agency concludes that its written comments on the DEIS warrant additional discussion for purposes of its action than that found in the lead agency's FEIS (in which case the agency may prepare a supplemental EIS at its own expense).

(4) Existing documents may be used for a proposal by employing one or more of the following methods:

(a) "Adoption," where an agency may use all or part of an existing environmental document to meet its responsibilities under SEPA. Agencies acting on the same proposal for which an environmental document was prepared are not required to adopt the document; or

(b) "Incorporation by reference," where an agency preparing an environmental document includes all or part of an existing document by reference.

(c) An addendum, that adds analyses or information about a proposal but does not substantially change the analysis of significant impacts and alternatives in the existing environmental document.

(d) Preparation of a SEIS if there are:

(i) Substantial changes so that the proposal is likely to have significant adverse environmental impacts; or

(ii) New information indicating a proposal's probable significant adverse environmental impacts.

New information provided by FOTC, and others strongly indicates significant adverse environmental impacts from the SS RNG project. These impacts may be direct, indirect, short term, long term, widespread and cumulative. An EIS is warranted.

(e) If a proposal is substantially similar to one covered in an existing EIS, that EIS may be adopted; additional information may be provided in an addendum or SEIS (see (c) and (d) of this subsection).

WAC 197-11-655 Implementation.

(1) See RCW 43.21C.020, 43.21C.030(1), 43.21C.060, 43.21C.075, and 43.21C.080.

(2) Relevant environmental documents, comments, and responses shall accompany proposals through existing agency review processes, as determined by agency practice and procedure, so that agency officials use them in making decisions.

(3) When a decision maker considers a final decision on a proposal:

(a) The alternatives in the relevant environmental documents shall be considered.

(b) The range of alternative courses of action considered by decision makers shall be within the range of alternatives discussed in the relevant environmental documents. However, mitigation measures adopted need not be identical to those discussed in the environmental document.

(c) If information about alternatives is contained in another decision document which accompanies the relevant environmental documents to the decision maker, agencies are encouraged to make that information available to the public before the decision is made.

Since the City of Sunnyside did not evaluate alternatives to the SS RNG proposal, the city cannot comply with WAC 197-11-655

WAC 197-11-680 Appeals.

*(1) **Introduction.** Appeals provisions in SEPA are found in RCW 43.21C.060, 43.21C.075 and 43.21C.080. These rules attempt to construe and interpret the statutory provisions. In the event a court determines that these rules are inconsistent with statutory provisions, or with the framework and policy of SEPA, the statute will control. Persons considering either administrative or judicial appeal of any decision which involves SEPA at all are advised to read the statutory sections cited above.*

*(2) **Appeal to local legislative body.** RCW 43.21C.060 allows an appeal to a local legislative body of any decision by a local nonelected official conditioning or denying a proposal under authority of SEPA. Agencies may establish procedures for such an appeal, or may eliminate such appeals altogether, by rule, ordinance or resolution. Such appeals are subject to the restrictions in RCW 36.70B.050 and 36.70B.060 that local governments provide no more than one open record hearing and one closed record appeal for permit decisions.*

FOTC has appealed to the Sunnyside City Council three times under WAC 197-11-680(2). The first appeal was on September 22, 2023, likely beyond the short 20 day window prescribed in the Sunnyside Municipal Code section 2.72

*(3) **Agency administrative appeal procedures.***

(a) Agencies may provide for an administrative appeal of determinations relating to SEPA in their agency SEPA procedures. If so, the procedures must comply with the following:

(i) The agency must specify by rule, ordinance, or resolution that the appeals procedure is available.

(ii) Appeal of the intermediate steps under SEPA (e.g., lead agency determination, scoping, draft EIS adequacy) shall not be allowed.

(iii) Appeals on SEPA procedures shall be limited to review of a final threshold determination and final EIS. These appeals may occur prior to an agency's final decision on a proposed action.

The June 22, 2023 MDNS was a final threshold determination. Pacific Ag/Sunnyside RNG supplemented their environmental checklist with addenda on October 8, 2023. The City of Sunnyside posted a signed Notice of Addendum on November 28, 2023, with a deadline for comments of December 5, 2023.

Frankly, FOTC is confused regarding timelines for appeals, but we submit comments today to make sure we do not miss deadlines. This results in excess paperwork and excess documentation.

(iv) An agency shall provide for only one administrative appeal of a threshold determination or of the adequacy of an EIS; successive administrative appeals on these issues within the same agency are not allowed. This limitation does not apply to administrative appeals before another agency.

(v) Except as provided in (a)(vi) of this subsection, the appeal shall consolidate any allowed appeals of procedural and substantive determinations under SEPA with a hearing or appeal on the underlying governmental action in a single simultaneous hearing before one hearing officer or body. The hearing or appeal shall be one at which the hearing officer or body will consider either the agency's decision or a recommendation on the proposed underlying governmental action. For example, an appeal of the adequacy of an EIS must be consolidated with a hearing or appeal on the agency's decision or recommendation on the proposed action, if both proceedings are allowed in agency procedures. If an agency does not provide for a hearing or appeal on the underlying governmental action (either a hearing on the agency's recommendation or an agency appeal hearing after the decision is made), the agency may not hold a SEPA administrative appeal, except as allowed under (a)(vi) of this subsection.

This section says, *appeal shall consolidate any allowed appeals of procedural and substantive determinations under SEPA with a hearing or appeal on the underlying governmental action in a single simultaneous hearing before one hearing officer or body.* It does not say that appeals must be made to Superior Court as the City of Sunnyside advises.

(vi) The following appeals of SEPA procedural or substantive determinations need not be consolidated with a hearing or appeal on the underlying governmental action:

(A) An appeal of a determination of significance;

(B) An appeal of a procedural determination made by an agency when the agency is a project proponent, or is funding a project, and chooses to conduct its review under SEPA, including any appeals of its procedural determinations, prior to submitting an application for a project permit. Subsequent appeals of substantive determinations by an agency with jurisdiction over the proposed project shall be allowed under the SEPA appeal procedures of the agency with jurisdiction;

FOTC's July 6, 2023 appeal of the June 22, 2023 MDNS was mostly procedural. We believe that the City of Sunnyside and the Port of Sunnyside are project proponents based on the two years of meetings with Pacific Ag, the sale of property to Sunnyside RNG, and the extreme efforts the city and the port have exerted to move the SS RNG project forward. Based on WAC 197-11-680 (3)(a)(vi)(B) the City of Sunnyside should not have cancelled the August 23, 2023 appeal hearing.

(C) An appeal of a procedural determination made by an agency on a nonproject action; and

(D) An appeal to the local legislative authority under RCW 43.21C.060 or other applicable state statutes.

(vii) If a county/city to which RCW 36.70B.110 applies provides for an administrative appeal, any such appeal of a procedural or substantive determination under SEPA issued at the same time as the decision on a project action shall be filed within fourteen days after a notice of decision under RCW 36.70B.130 or after other notice that the decision has been made and is appealable. In order to allow public comment on a DNS prior to requiring an administrative appeal to be filed, this appeal period shall be extended for an additional seven days if the appeal is of a DNS for which public comment is required under this chapter or under county/city rules adopted under SEPA. For threshold determinations issued prior to a decision on a project action, any administrative appeal allowed by a county/city shall be filed within fourteen days after notice that the determination has been made and is appealable. Nothing in this subsection alters the requirements of (a)(v) and (vi) of this subsection.

(viii) Agencies shall provide that procedural determinations made by the responsible official shall be entitled to substantial weight.

(b) Agencies providing for administrative appeals shall provide for a record as required by RCW 43.21C.075 (3)(c).

(c) If an agency provides an administrative appeal procedure, that procedure must be used before anyone may initiate judicial review of any SEPA issue that could have been reviewed under the agency procedures.

The City of Sunnyside provides an administrative appeal procedure under Sunnyside Municipal Code Section 2.46 and 2.72. FOTC believes the City of Sunnyside erred by cancelling our August 23, 2023, appeal and telling us that our only option was to appeal permit decisions in Superior Court. WAC 197-11-680 (3)(c) says differently.

(4) Judicial appeals.

(a) SEPA authorizes judicial appeals of both procedural and substantive compliance with SEPA.

(b) When SEPA applies to a decision, any judicial appeal of that decision potentially involves both those issues pertaining to SEPA (SEPA issues) and those which do not (non-SEPA issues). RCW 43.21C.075 establishes time limits for raising SEPA issues, but says that existing statutes of limitations control the appeal of non-SEPA issues. The statute contemplates a single lawsuit.

(c) If there is a time limit established by statute or ordinance for appealing the underlying governmental action, then appeals (or portions thereof) raising SEPA issues must be filed within such time period.

The Sunnyside City Code states:

2.72.010 Appeal period.

Any appeal from any action of the City Council, City Commission or City Board, or City official or employee, whose decisions are not directly appealable to the City Council, must be brought within 20 days from the date of the effective date of the action appealed from. [Ord. 1313 § 1, 1981.]

The City of Sunnyside issued an MDNS for the SS RNG project. FOTC timely appealed. The city cancelled the appeal. After the threshold determination, SS RNG submitted changes to the environmental checklist that will affect the MDNS. FOTC may comment, but there is apparently no pathway for an appeal, according to the Sunnyside Municipal Code.

The City of Sunnyside may have designed a trap in which appeals were postponed and then prohibited due to postponement.

(d) The notice of action procedures of RCW 43.21C.080 may still be used. If this procedure is used, then the time limits for judicial appeal specified in RCW 43.21C.080 shall apply, unless there is a time limit established by statute or ordinance for appealing the underlying governmental action. If so, the time limit for appeal of SEPA issues shall be the time limit in the statute or ordinance for the underlying governmental action. If the proposal requires more than one governmental decision that will be supported by the same SEPA documents, then RCW 43.21C.080 still only allows one judicial appeal of procedural compliance with SEPA, which must be commenced within the applicable time to appeal the first governmental decision.

(e) If the time limit established by statute or ordinance for appealing the underlying governmental action is less than fifteen days, then the notice of action in RCW 43.21C.080(1) may be given by publishing once within that shorter time period, in a newspaper of general circulation in the area where the property that is the subject of the action is located, and meeting the other requirements of RCW 43.21C.080.

(f) If there is no time limit established by statute or ordinance for appeal, and the notice of action provisions are not used, then SEPA provides no time limit for judicial appeals. Appeal times may still be limited, however, by general statutes of limitation or the common law.

(g) For the purposes of this subsection, "a time limit established by statute or ordinance" does not include time limits established by the general statutes of limitation in chapter 4.16 RCW.

(5) Official notice of the date and place for commencing a judicial appeal.

(a) Official notice of the date and place for commencing an appeal must be given if there is a time limit established by statute or ordinance for commencing an appeal of the underlying governmental action. The notice shall include:

(i) The time limit for commencing appeal of the underlying governmental action and SEPA issues, and the statute or ordinance establishing the time limit; and

(ii) Where an appeal may be filed.

(b) Notice is given by:

(i) Delivery of written notice to the applicant, all parties to any administrative appeal, and all persons who have requested notice of decisions with respect to the particular proposal in question; and

(ii) Following the agency's normal methods of notice for the type of governmental action taken.

(c) Written notice containing the information required by subsection (5)(a) of this section may be appended to the permit, decision documents, or SEPA compliance documents or may be printed separately.

(d) Official notices required by this subparagraph shall not be given prior to final agency action.

As noted above, FOTC is not certain of the intent of the City of Sunnyside's Notice of SEPA Addendum. FOTC could engage better if we knew whether these addenda would result in changes to the MDNS and consequently in final agency action.

The Notice of SEPA Addendum provides a window for public comments, but does not describe an appeal procedure. We understand that the lead agency has an obligation to evaluate and respond to our comments. See WAC 197-11-340 (2)(f)

WAC 197-11-910 Designation of responsible official.

Agency SEPA procedures shall designate or provide a method of designating the responsible official with speed and certainty (WAC 197-11-906 (1)(d)). This designation may vary depending upon the nature of the proposal. The responsible official shall carry out the duties and functions of the agency when it is acting as the lead agency under these guidelines. Since it is possible under these rules for an agency to be acting as a lead agency prior to actually receiving an application for a license to undertake a private project, designation of the first department within the agency to receive an application as the responsible official will not be sufficient.

It is FOTC's understanding that Trevor Martin from the City of Sunnyside is the responsible official for this SEPA determination.

WAC 197-11-924 Determining the lead agency.

(1) The first agency receiving an application for or initiating a nonexempt proposal shall determine the lead agency for that proposal, unless the lead agency has been previously determined, or the agency receiving the proposal is aware that another agency is determining the lead agency. The lead agency shall be determined by using the criteria in WAC 197-11-926 through 197-11-944.

(2) If an agency determines that another agency is the lead agency, it shall mail to such lead agency a copy of the application it received, together with its determination of lead agency and an explanation. If the agency receiving this determination agrees that it is the lead agency, it shall notify the other agencies with jurisdiction. If it does not agree, and the dispute cannot be resolved by agreement, the agencies shall immediately petition the department of ecology for a lead agency determination under WAC 197-11-946.

(3) Any agency receiving a lead agency determination to which it objects shall either resolve the dispute, withdraw its objection, or petition the department for a lead agency determination within fifteen days of receiving the determination.

(4) An applicant may also petition the department to resolve the lead agency dispute under WAC 197-11-946.

(5) To make the lead agency determination, an agency must determine to the best of its ability the range of proposed actions for the proposal (WAC 197-11-060) and the other agencies with jurisdiction over some or all of the proposal. This can be done by:

(a) Describing or requiring an applicant to describe the main features of the proposal;

(b) Reviewing the list of agencies with expertise;

(c) Contacting potential agencies with jurisdiction either orally or in writing.

It is FOTC's understanding that Pacific Ag/Sunnyside RNG may have approached Yakima County with this proposal prior to contacting the City and Port of Sunnyside.

WAC 197-11-92 Lead agency for governmental proposals.

(1) When an agency initiates a proposal, it is the lead agency for that proposal. If two or more agencies share in the implementation of a proposal, the agencies shall by agreement determine which agency will be the lead agency. For the purposes of this section, a proposal by an agency does not include proposals to license private activity.

(2) Whenever possible, agency people carrying out SEPA procedures should be different from agency people making the proposal.

WAC 197-11-928 Lead agency for public and private proposals.

When the proposal involves both private and public activities, it shall be characterized as either a private or a public project for the purposes of lead agency designation, depending upon whether the primary sponsor or initiator of the project is an agency or from the private sector. Any project in which agency and private interests are too intertwined to make this characterization shall be considered a public project. The lead agency for all public projects shall be determined under WAC 197-11-926.

The City of Sunnyside's May 17, 2023 Notice of Environmental Review stated:

NOTICE OF ENVIRONMENTAL REVIEW This is to notify agencies with jurisdiction and environmental expertise and the public that the City of Sunnyside, Planning Division, has been established as the lead agency, under WAC § 197-11-928 for this project. The City of Sunnyside has reviewed the proposed project for probable adverse environmental impacts and expects to issue a Determination of Nonsignificance (DNS) per WAC § 197-11-355. The proposal may include mitigation measures under applicable codes and the project review process may incorporate or require mitigation measures regardless of whether an EIS is prepared. A copy of the subsequent threshold determination may be obtained by request and may be appealed pursuant to SMC Ch. 18.04.

Because this notice cited WAC 197-11-928, FOTC assumed this to be a public and private proposal. FOTC asked the City of Sunnyside several times whether it is a public and private project or a private project. The city did not answer. At a November 30, 2023 public meeting regarding the project, Harrison Pettit from Pacific Ag assured us several times that it is a private project. If this is so, then the City of Sunnyside was incorrect in

assuming the lead agency role, at least under WAC 197-11-928. FOTC asserts that the City of Sunnyside has an obligation to provide the public with accurate information.

WAC 197-11-930 Lead agency for private projects with one agency with jurisdiction.

For proposed private projects for which there is only one agency with jurisdiction, the lead agency shall be the agency with jurisdiction.

FOTC has asked the City of Sunnyside to list agencies with jurisdiction for the SS RNG project. The city has not answered.

* * * * * * * *

There are errors in the documents posted for this project:

- In the November 16, 2022, and May 17, 2023 Notice of Environmental Reviews the City of Sunnyside stated:

The City of Sunnyside has reviewed the proposed project for probable adverse environmental impacts and expects to issue a Determination of Nonsignificance (DNS) per WAC § 197-11-355.

But the City of Sunnyside has not incorporated WAC 197-11-355 by reference.

- In the November 16, 2022, and May 17, 2023 Notice of Environmental Reviews the City of Sunnyside stated:

This is to notify agencies with jurisdiction and environmental expertise and the public that the City of Sunnyside, Planning Division, has been established as the lead agency, under WAC § 197-11-928 for this project.

But WAC 197-11-928 refers to public and private projects. Sunnyside RNG claims this is a private project.

- Tax Parcel Numbers are listed as:
    - Notice of Environmental Review TAX PARCEL NUMBER(S): 220901-13001, -44401, -41404
    - Mitigated Determination of Non-Significance Parcel Number(s): 220901-13001, -44401, & -41404
    - Notice of Appeal Cancellation TAX PARCEL NUMBER(S): 220901-13001, -44401, -41404
    - Notice of SEPA Addendum TAX PARCEL NUMBER(S): 22090-141405 & 220901-41406 (Previously 220901-13001, -44401, - 41404)

- When did these changes occur? FOTC asks because we have spent many, many hours trying to make sense of the property location and zoning.

- Many related documents list two different File Numbers: SEPA-2022.0200 & SEPA 2023.0200 for the same project

- The October 8, 2023 Addendum Letter from Sunnyside RNG to the City of Sunnyside references File Number 2022.0200

- The October 8, 2023 Addendum Letter from Sunnyside RNG to the City of Sunnyside references Exhibit B, *A Cultural Resources Survey for the Sunnyside RNG project*. This document has not been posted for public view.

- The October 8, 2023 Addendum Letter from Sunnyside RNG to the City of Sunnyside also identifies Exhibit B as a *Traffic Impact Analysis*

- The signature date for this letter is November 8, 2023, while the heading date for the letter is October 8, 2023

- The November 28, 2023 Notice of SEPA Addendum says:

  There is a 14-day comment period for this review. This may be your only opportunity to comment. All written comments received by 5:00 p.m. on December 5, 2023. Please reference file numbers (SEPA-2022.0200) and applicant's name (Sunnyside RNG) in any correspondence you submit.

  We are not sure this is the correct File Number.

The Friends of Toppenish Creek appreciate this opportunity to comment on SEPA review for the SS RNG project. We request clarification on next steps, specifically the appeal process as interpreted by the Lead Agency, the City of Sunnyside.

Sincerely,

Jean Mendoza

SUNNYSIDE RNG
Renewable Natural Gas Project
Introduction to the Port of Sunnyside
September 6, 2022

www.pacificag.com

Who We Are

- Sunnyside RNG is owned and will be operated by Pacific Ag Renewables (PAR)
- PAR is a wholly owned subsidiary of Pacific Ag, North America's largest hay and crop residue harvest and supply company with operations in 27 states.
- Pacific Ag was established in 1998 in the Columbia basin with offices in the Tri-Cities, WA and Hermiston, OR.
- Pacific Ag is locally owned with deep roots in the Oregon and Washington farm economy for many generations.
- Pacific Ag brings deep operational expertise in ag processing, materials supply and logistics/trucking
- Sunnyside RNG's financial and technology partners bring decades of experience in the US and Europe with anaerobic digestion and renewable natural gas production.

The Project: Sunnyside RNG

Sunnyside RNG will:

- Turn agricultural waste products into renewable natural gas (RNG), a low-carbon substitute for fossil natural gas to be used as a biofuel in the transportation sector.
- Produce 830K MMBtus per year of RNG – making it one of the largest ag waste anaerobic digesters in the nation.
- Divert dairy manure from the lagoons of 15-20 medium to small dairies that otherwise would produce odors and methane off-gasses, and crop waste that might otherwise be burned or produce CO2 from decomposition.
- Produce an organic digestate that can be used as fertilizer, livestock bedding and compost.

Community Benefits

Economic (as calculated by the Yakima County Development Association)

A Significant Investment in the Sunnyside Community

Plant Cost: $94 - $100 million

Jobs:

- 29 full-time direct plant positions at an average wage of $68,379 (from a $2 million annual payroll)
- 15 direct trucking jobs and an estimated 26 indirect jobs in the community.
- median annual income Yakima County is $39,172 (source: Employment Security Department of Washington State, 2021 data)

Taxes: $6 million annually in direct and indirect taxes to local and state agencies to support schools and other community services.

Community Benefits

Environmental

- Recycles manure and kills odors and pathogens while producing a renewable fuel and soil products.
- Moving manure from open lagoons to an airtight biogas system reduces both odors and GHG emissions.
- Replaces fossil-based diesel with low-carbon, renewable natural gas as a biofuel for CNG fleets.
- Recycling manure creates an opportunity to separate nutrients and keep them out of the waterways.

Sunnyside RNG is fully funded and will begin construction in late 2022 with first RNG production commencing in the 1st quarter of 2024

Anaerobic Digesters and Biogas Safety

https://farm-energy.extension.org/anaerobic-digesters-and-biogas-safety/

When manure is anaerobically digested, the biogas produced is primarily composed of methane and carbon dioxide, with lesser amounts of hydrogen sulfide, ammonia, and other gases. Each of these gases has safety issues. Overall, biogas risks include explosion, asphyxiation, disease, and hydrogen sulfide poisoning.

Image: US Municipal Supply Company.

Extreme caution is necessary when working with biogas. Adequate ventilation, appropriate precautions, good work practices, engineering controls, and adequate personal protective equipment will minimize the dangers associated with biogas. Wherever possible, digester-associated tasks and maintenance should be performed without anyone having to enter confined spaces, including pits. Systems should be initially designed so that confined space entry is not required to perform maintenance.

The information presented here is for reference purposes only. No liability is implied.

Biogas Hazards

Fire/Explosion

Methane, approximately 60% of biogas, forms explosive mixtures in air. If biogas is diluted between 10% and 30% with air, there is an explosion hazard. In 2003, several explosions on Canadian swine farms were thought to have been caused by the methane in biogas exploding (Choinière, 2004). Hydrogen sulfide and ammonia are also potentially explosive.

Because of the explosion hazards, no open flames should ever be used near a digester. Also, equipment such as large engines and electric generators must be suitable to the environment so a

spark will not ignite the gas. Explosion-proof equipment and electrical service, as well as non-sparking tools, should be used around digesters and biogas. There must be no smoking near the digester or related biogas lines and equipment.

Asphyxiation

Asphyxiation from biogas is a concern in an enclosed space where manure is stored. Osbern and Crapo (1981) report one case of three people who died from asphyxiation created by swine manure gas in an enclosed space. Even open-topped manure pits can generate methane at a sufficient rate to push out the air above the manure and render the space oxygen-deficient.

Never enter a facility where manure is stored or where there is a suspected biogas leak as natural ventilation cannot be trusted to dilute the explosion hazard sufficiently. Airing out a facility does not impart safety, as some of the gases produced are heavier than air. If a person is found unconscious in such a facility, do not enter the facility because you may be overcome as well. Contact emergency services so that firefighters wearing self-contained breathing apparatus (SCBA) can safely retrieve the victim.

Disease

Animal manure contains bacteria, viruses and, possibly, parasites. Biogas is generated by the anaerobic digestion of manure, which occurs because of the bacteria present in animal wastes, some of which can produce infection. When handling waste material, exercise appropriate precautions by using personal protective equipment to avoid contact with manure. Washing after working around the digester is recommended. It is particularly recommended to wash hands before eating and drinking and before touching the eyes or other mucous membranes.

Keeping the digester facility clean will reduce disease hazards as well as the spread of odors and fly populations in the digester facility.

Components of Biogas

Biogas consists mainly of 60% methane and 40% carbon dioxide, with low levels of hydrogen sulfide and other gases. Each of these gases can displace oxygen.

Methane

Methane is lighter than air and will collect toward the upper spaces of the building. It is explosive at 5% to 15% concentrations. While methane is not a toxic gas, it displaces air so that, in a confined space, it creates an oxygen-deficient atmosphere. This is how it kills.

Carbon Dioxide

Carbon dioxide is an odorless gas that is heavier than air. In a quiescent space, carbon dioxide can layer near the floor. Slightly elevated levels of carbon dioxide increase heart rate and respiration rate. Higher levels displace oxygen supply in the bloodstream, which can cause unconsciousness and death.

Hydrogen Sulfide

Hydrogen sulfide is a highly toxic gas that is heavier than air. At very low levels, it smells like rotten eggs and can produce eye irritation. At dangerous levels, it destroys the sense of smell and produces respiratory paralysis. Thus, at dangerous and fatal levels, where one can literally drop dead, there is no odor to warn of its presence.

The following table shows the health effects of hydrogen sulfide at different concentrations.

Parts per million (ppm)	Possible health effects
0.01-0.3	Odor is detectable
1-10	Moderate to strong odor Nausea Tears Headaches Sleep loss
10-150	Irritation of the eyes Irritation of the lungs
150-750	Severe health effects Death becomes more likely
>750	Death may occur in minutes

Ammonia

Ammonia is a gas that is lighter than air, has a pungent odor, and can irritate the eyes and respiratory tract. Ammonia can displace oxygen in the bloodstream.

Precautions

Manufacturer Warnings

Failure to heed manufacturer warnings may result in death or serious injury. Contact the manufacturer for maintenance and service requirements and availability of service.

Safety Walk-Throughs

A safety walk-through can help you determine potential hazards and preventative measures. Cornell University developed a comprehensive self-assessment guideline for farmers. It is intended to be used by farm owners and managers or farm staff who are responsible for the operations and/or maintenance of anaerobic digesters and their related processes. It provides guidance for process and job evaluation with suggestions based on typical potential hazards for farm digester systems and their associated preventative measures.

Gas Sensors

Explosion, suffocation, and poisonous gas hazards may be detected using gas sensors. These sensors include both disposable and electronic sensors. Electronic sensors need testing regularly, and these sensors may have a disposable component that needs periodic replacement. Only qualified people should use these sensors to determine if an area is safe.

Personal Protective Equipment

An area where manure is stored should never be entered without the appropriate personal protective equipment, which may include a self-contained breathing apparatus (SCBA). The use of protective equipment such as an SCBA is covered by OSHA regulations, and the operator must be certified in its use with equipment-fit testing and medical clearance.

Workers in Iowa failed to investigate leak that poured manure wastewater into creeks

https://www.kcur.org/2022-07-06/workers-in-iowa-failed-to-investigate-a-leak-that-poured-manure-wastewater-into-the-rock-river

KCUR | By Kavahn Mansouri

Iowa Department Of Natural Resources

Drone photos taken of the confluence of Lizard Creek and Mud Creek after thousands of gallons of manure water leaked from a manure digester upstream.

Workers at a manure digester in northwest Iowa did not act on signs of a potential leak before thousands of gallons of wastewater poured into nearby waterways, according to documents from the state's environmental regulator.

In early February, a manure digester owned and operated by Colorado-based biofuel company Gevo. Inc.leaked approximately 376,000 gallons of manure water into creeks near Winding Meadow Dairy, roughly 60 miles north of Sioux City. The spill caused E. coli readings to spike in nearby streams and Rock River.

Last week the Iowa Department of Natural Resources (DNR) fined Iowa dairy farmer Terry Van Maanen $10,000 for the spill, the maximum amount the department can impose. Gevo Inc. has not been fined for the incident.

Van Maanen owns Winding Meadow Dairy, where the digester is located. At the time of the spill, the digester was operating without permission from the state, due to a lack of construction certifications.

Neither Gevo Inc. nor Van Maanen immediately returned a request for comment.

Manure digesters, or anaerobic digesters, break down cow manure through a process called anaerobic digestion. According to the Environmental Protection Agency, the process creates biogas used for electricity, heat, compressed natural gas and vehicle fuel.

According to an administrative order from DNR, warning signs of a leak were not investigated before the spill. Documents show workers noted the fluid level in the digester dropped by five feet when liquid was first added to the digester.

Without any further investigation into the cause, more liquid was added to the digester, according to the findings.

Van Maanen and Gevo Inc. later discovered that improperly sealed control joints likely caused the leak, according to DNR's findings. The joints have since been repaired.

Devyn Hall, a farming and environmental community organizer with Iowa Citizens for Community Improvement, said DNR's $10,000 maximum isn't enough. Hall said DNR's maximum fine is too low and doesn't do enough to discourage future spills.

"We see this so often with manure spills and factory farms — we have repeat violators, we have massive spills and they don't get the fines that they deserve," Hall said. "Even in this case, $10,000 for the amount spilled doesn't add up."

The amount of manure water spilled from the digester could fill roughly 18 swimming pools.

Iowa Citizens for Community Improvement pressed Iowa Attorney General Tom Miller to pick up the case and levy higher charges against Gevo Inc. and Van Maanen. In certain cases, the attorney general's office can take on cases referred to the office by the DNR to access higher charges and fines than the DNR's maximum amount.

Hall said the group sent 350 emails urging DNR and Miller's office to seek further enforcement.

In the end, Miller's office didn't take the case. Even so, Hall said the fine carries meaning. They said it's a sign that pressuring DNR and the attorney general's office worked.

"Getting that news was inspiring," Hall said. "We had a feeling the fine would be much lower, but it turns out the pressure worked. If we have people pressuring the DNR and the attorney general saying 'Hey, we're watching,' then maybe we can get these small wins."

Gevo Inc. owns three manure digesters in northwest Iowa, including the digester at Winding Meadows Dairy. The company recycles biogas from dairy farms' manure and processes it into renewable natural gas to be sold in California, touting the projects as environmentally friendly.

According to a company filing with the Securities and Exchange Commission in June, two other incidents at Gevo Inc. owned manure digesters in Northwestern Iowa occurred in April. Both incidents resulted in the “accidental discharge of very small amounts of water and manure into the environment.”

The filing states Iowa DNR may file further financial sanctions against Gevo Inc. concerning the spills but notes the fees wouldn't greatly impact the company financially.

Of the 376,000 gallons of manure water leaked into the nearby creeks in early February, DNR reported Gevo contractors removed 48,525 gallons of slurry water, a mixture of sediment and water, from the area deposited into a nearby lagoon.

In the days following the spill, E. coli levels in downstream creeks and the nearby Rock River spiked.

E. coli is a bacteria found in bodies of water exposed to human or animal waste. When ingested, the bacteria can cause mild to life-threatening symptoms in humans.

The investigation found that E. coli levels in Lizard Creek, where most of the manure water leaked into, were roughly nine times higher two days after the leak.

Mud Creek's E. coli readings also increased in the days following the leak, exceeding Iowa DNR's surface water standards. Lizard Creek does not have a listed average, according to the state.

The two creeks feed to Rock River, where E. coli levels steadily increased in the days following the leak but did not exceed surface water standards.

The E. coli levels in all three bodies of water steadily trailed off in the weeks following the leak.

Jacob Simonsen, a wastewater specialist with DNR, said the winter weather and frozen creeks near the digester helped contain some of the waste.

"You never want to see anything like this happen but it wasn't as potent of a release as it could have been," Simonsen said.

This story comes from the Midwest Newsroom, an investigative journalism collaboration including IPR, KCUR 89.3, Nebraska Public Media News, St. Louis Public Radioand NPR.

Company filled massive manure container despite signs of a leak, DNR says

https://iowacapitaldispatch.com/2022/07/06/company-filled-massive-manure-container-despite-signs-of-a-leak-dnr-says/

BY: JARED STRONG **- JULY 6, 2022 5:00 PM**

A manure digester near Rock Valley lies mostly underground and can hold up to 1.5 million gallons of manure. (Photo by Jacob Simonsen/Iowa DNR)

A northwest Iowa facility that captures biogas from cow manure began leaking when it was first filled in January, but its operators ignored indications of the leak and filled it further, according to the Iowa Department of Natural Resources.

An estimated 376,000 gallons of manure mixed with water leaked from a manure digester near Rock Valley. The digester is one of three in that part of the state built by Colorado-based Gevo, which processes the methane it captures from dairy farm manure into renewable natural gas to power low-emissions vehicles in California.

“When the liquid was first added to the digester, it was noted that the level dropped by five feet,” according to a recent DNR order that fined the dairy farm owner for the leak. “No investigation to the cause was done at the time and then more liquid was added to the digester.”

Farm owner Terry Van Maanen was fined $10,000 because he has ultimate responsibility over the facility's operation, the DNR said, regardless of who actually operates it.

Gevo operators initially believed that the drop was caused by foam dissipating at the surface of the water, the order said.

The facility can hold up to about 1.5 million gallons of manure. It leaked into the ground for up to three weeks before someone noted another surface drop of more than two feet and saw manure flowing from an underground tile line into a field and Lizard Creek.

Gevo reported the leak to the DNR on Feb. 7. It's unclear how much of the water flowed into the creek. There was no apparent fish kill, but tests of the water showed elevated levels of bacteria and ammonia.

The facility is located at Winding Meadows Dairy, which has about 2,400 cows, according to DNR data. The digester is a large, mostly underground container that captures the gas released by microorganisms as they feed on the manure. The gas is compressed and transported through a few miles of pipe to another facility, where it is refined and injected into an interstate natural gas pipeline.

To fix the problem, Gevo put a layer of epoxy in areas of the container most likely to leak, said Jacob Simonsen, an environmental specialist for the DNR who investigated the leak. He said the facility is now operational.

Gevo announced last month that it has begun injecting the processed gas into the interstate pipeline. The company said it is producing the gas from the manure of more than 20,000 cows from three dairy farms. The Rock Valley site is the smallest.

“The success that Gevo is achieving in northwest Iowa right now is the result of the team of dedicated people who are working to change the world by converting waste into useful energy, animal bedding, and soil fertilizer,” Gevo President Chris Ryan said in a press release.

State-financed manure digester plagued by spills, explosion

Company not sure if it wants to stick with Dane County project

Nearly 400,000 gallons of manure flowed from a Dane County biodigester after a pipeline broke in 2013. The Waunakee project to generate electricity and remove phosphorus is the first of its kind in Wisconsin, but has fallen short of expectations. Credit: Wisconsin Department of Natural Resources

Jan. 29, 2015

https://archive.jsonline.com/news/statepolitics/state-financed-manure-digester-plagued-by-spills-explosion-b99435123z1-290263421.html

By Lee Bergquist of the Journal Sentinel

An experimental project in Dane County designed to capture livestock waste that pollutes Lake Mendota has been hit by a litany of troubles, including manure spills and a 2014 incident that caused a fire and methane gas explosion.

A state-financed manure digester system near Waunakee is the first of its kind in Wisconsin. It has been touted by supporters, including Dane County

officials, for generating electricity, limiting the spreading of excess cattle manure and reducing emissions of greenhouse gases.

But the $12 million system — financed with $3.3 million in state funds — has fallen far short of expectations.

In three years, pipeline breaks have caused three manure spills, totaling more than 400,000 gallons. In August, an explosion of methane gas knocked the roof off one of the digesters, sending smoke billowing high into the air.

The state Department of Natural Resources started enforcement action against the developer, Milwaukee-based Clear Horizons, for the spills, lax record keeping and violating agreements to remove a key pollutant from the manure. In November, the DNR referred the matter to Justice Department lawyers for prosecution, documents show.
Despite the subsidy, Clear Horizons said that it had lost $2.8 million since the start of the project in late 2010, according to the DNR in a March 25, 2014, document reviewing the company's troubles.

Since September, a Clear Horizons official said the company has spent more than $1 million on repairs and other changes.

Once all problems have been addressed, Norman Doll said this week that his parent company, PPC Partners Inc., might exit the business entirely. Clear Horizons has built one other digester at a farm near Waterloo in Jefferson County.

"No question, there were mistakes made on our part," said Doll, a former president of Pieper Electric, a subsidiary of PPC Partners Inc., who was brought in last year as troubles mounted.

"Any incident by itself wouldn't have looked so bad. But when you couple them together, it's definitely a problem."

A Variety Of Hurdles

Clear Horizons' troubles underscore the financial and operational hurdles that can arise involving projects managing vast amounts of manure.

The operations, located in the Town of Vienna, include three manure digesters that capture methane, a greenhouse gas. The gas is used for combustion to generate electricity, which is sold. Manure, a source of methane, is piped from three neighboring dairy farms.
Wisconsin ranks near the top in states with anaerobic digesters.

The big difference with the Clear Horizons operation is the installation of other equipment to remove phosphorus from the manure.

Manure is agriculture's most basic of fertilizers. But when applied in excess, or improperly, phosphorus and nitrogen can release a bumper crop of nutrients, which have long plagued Madison-area lakes.

The Yahara River watershed violates state water quality standards for phosphorus, and local officials are required by state law to take steps to turn things around in a county with an estimated 50,000 dairy cows.

Amid that backdrop, the administration of former Gov. Jim Doyle, a Democrat, provided county officials $6.6 million in help to finance the start-up of the Waunakee digester, which went into operation in late 2010, and a second, near Middleton.

The digester in the Town of Springfield near Middleton involves Gundersen Health System of La Crosse. The operator of hospitals and clinics is using the digester to reduce energy costs. Like the Clear Horizons operation, the Gundersen plant has also been outfitted with equipment to remove phosphorus.

The Gundersen facility, which started operating last year, isn't experiencing environmental problems, the DNR said.
It's a different story with Clear Horizons.

The company is obligated to remove 60% of the phosphorus from manure in its agreement with county and state officials. That's not happening, the DNR says.

In 2011, the average removal rate was 63%; in 2012 it was 56%; in 2013, it plummeted to 44%, documents from an enforcement conference with the company show. In some weeks this past December, as little as 23% of the phosphorus was being removed, records show.

The phosphorus is removed by using a centrifuge to separate the solids and liquids. The solids, with 60% of the phosphorus, are dried into a product sold for bedding material for cattle outside the watershed, according to Doll.

As for the spills, the biggest occurred in November 2013 when a pipe ruptured, sending an estimated 380,000 gallons of waste into a nearby stream, documents submitted by the company to the DNR show.

Two smaller spills occurred in March and July of last year. The company says the manure never left the site. The spills were caused by faulty pipe design and the pipes have been replaced.

Clear Horizons estimates that little phosphorus ever entered local waterways and that an estimated 80 tons of phosphorus have been kept out of the Dane County waters in the past three years.

Then came the explosion, which knocked off the roof made of a lightweight membrane material. Doll said workers used a fan to inflate the roof after cleaning.

"The assumption was made that since the valves were closed, there would be no methane gas in the tank," Doll said. "That was a bad assumption."

Another mistake: The fan was a type that can produce sparks.

"It blew up and started the roof on fire," Doll said.

Doll, who worked for Pieper for 28 years, took over the project shortly after the explosion and replaced the top managers. The plant now has employees on the job around the clock in the event of other mishaps.

DNR Allegations Disputed

Clear Horizons says it disagrees with the DNR on the extent of the company's failure to cut phosphorus and has explained that a design flaw that recirculates wastewater from one of the farms is making the situation look worse than it is. The DNR disputes this.

There have been numerous meetings with the state and the county as the problems have mounted.

"There is no excuse — there were management missteps," said David Merritt, Dane County's director of policy and program development. "But we firmly believe the facility will be brought into compliance this year."

The experience has soured the company on the business, but Doll envisions a market for disposing manure that Dane County's watershed can't accommodate.

"If someone comes along and says we'll buy it for this amount, and it was a good offer, we would certainly consider it," Doll said.

Many of the assumptions the company made at the start were wrong.

In the future, the business model will have to be tweaked, and farmers sending manure to comparable operations may need to pay the plant to accept it, he said.

Under the existing system, Clear Horizons takes it for free.

Waunakee Manure Digester has second spill in two months; company now says it has a fix

https://agupdate.com/news/local/environment/waunakee-manure-digester-has-second-spill-in-2-months-company-now-says-it-has-a/article_7a89ed83-bc26-581d-9d83-db9ff707413c.html

JEFF GLAZE and STEVE VERBURG | Wisconsin State Journal | |

For the second time in two months, a short section of above-ground pipe burst at a biodigester near Waunakee, discharging thousands of gallons of animal waste.

Meanwhile, the biodigester operators said Wednesday they were told by a consultant last week of a fix that probably would have prevented both releases.

“We were evaluating the engineering proposal and preparing a recommendation to present to the DNR and Dane County,” said Jim Ditter, CEO of PPC Partners, which owns the Clear Horizons biodigester.

About 20,000 gallons spilled onto the ground at about 4 p.m. Monday, said county lakes and watersheds director Kevin Connors, who visited the site Tuesday. Workers stopped the breach within 15 minutes, and the manure flowed into a retention basin without reaching waterways outside of the biodigester property on Cuba Valley Road, Connors said.

“Fortunately they had people on the site this time and we didn’t have as big a mess as we did last time,” said Josh Wescott, chief of staff to Dane County Executive Joe Parisi.

The Clear Horizons facility has been scrutinized since Nov. 24 when 300,000 gallons spilled and at least some flowed a mile away to reach Six Mile Creek, which leads to Lake Mendota.

Biodigesters produce electricity and reduce the nutrients in dairy manure that farmers spread on fields as fertilizer.

Those nutrients make their way into rivers and lakes. In Madison they have contributed to algae blooms, unpleasant odors and bacteria-tainted water that forces beach closings.

Ditter said spills on Nov. 24 and again on Monday appear to have happened the same way — an equipment vibration or shift in the soil fractured a fitting on a short length of curved pipe leading from a pump house to underground lines that feed the digesters.

The Nov. 24 spill was far larger because it happened at 11 p.m. Manure backwashed out of the digester tank for roughly six hours until an employee arrived for work in the morning. Alarms and monitoring devices failed to activate, the plant manager said at the time.

The Clear Horizons facility features three 1.25 million-gallon digester tanks surrounded by protective berms. But both ruptures occurred at a pump house 200 feet outside the berm.

On Wednesday, hours after the county executive's office brought the second spill to light, the company announced it had a fix for the pipe malfunctions.

"Ground settling or slight pipe movement caused susceptible pipes to fail at the elbow," spokesman Leo Maney said in a statement. "Clear Horizons is immediately implementing corrective actions to install flexible connectors at the elbows of these pipes to prevent future failures."

"It cost approximately $650 for each flexible elbow and we have identified 20 elbows that need replacing," Ditter said in an email to the State Journal on Wednesday. "The order was placed today."

The company also is evaluating electronic safety controls and making plans to add monitoring devices that would help isolate ruptures and shut down the system in the event of a problem, Maney's statement said.

Major spills

As livestock operations in Wisconsin continued to grow in 2013, about 1 million gallons of manure was spilled, more than in any year since 2007, state Department of Natural Resources records show. The DNR responds to about 50 spills each year.

The Nov. 24 Clear Horizons spill and another 300,000-gallon discharge on Feb. 5 at the UW-Madison's Arlington Agricultural Research Station were two of the four largest spills in the last 15 years, a DNR database shows.

The State Journal reported in December that there were many similarities between the large spills at the UW-Madison research station and Clear Horizons.

The UW-Madison pipe rupture happened at 3 a.m. when no employees were present. It continued for hours before employees arrived at work in the morning. An unknown amount of manure eventually reached the Yahara River.

The break occurred in a short section of above-ground pipe similar to the rupture point at each of the Clear Horizons incidents. Vibrations from a pump broke a fitting on the pipe.

UW-Madison responded by building a berm to channel any future spill into a lagoon, installing a $3,000 automatic shutoff valve, and

replacing a short length of old chain that broke. For years, it had held the pipe steady when a pump kicked on.

A call for safeguards

“It doesn’t take much runoff to cause a lot of algal growth, so incidents like these suggest that all manure digesters should be required to install measures like automatic shutoff valves that will kick in when a pressure drop is detected and berms to reduce the risk of manure running into nearby streams, rivers and lakes,” said Shahla M. Werner, director of the Sierra Club’s Wisconsin chapter.

The Madison-based Clean Lakes Alliance urged the company and the DNR to ensure proper safeguards.

“We cannot play Russian roulette with our lakes,” the alliance said in a statement. “The gamble is too great.”

Before the Monday incident, Clean Horizons was already scheduled to meet Thursday with county officials to discuss last year’s spill.

Until their statement Wednesday, the digester operators hadn’t answered questions Parisi raised in November about whether they have adequate staffing and equipment, Wescott said.

In a letter sent Tuesday, Parisi requested that Clear Horizons “thoroughly review and modify” its current operational plan, review of staffing levels, procedures, safety features and “most critically — whether the most effective personnel resources and expertise are being utilized.”

Reports on the November spill have been forwarded to DNR enforcement staff, but no determination on any fine or other action has been decided, agency spokesman Bob Manwell said.

No fish kills were reported after that spill. Area farmers and contractors worked for days to pick up the manure and spread it on farm fields, county officials said.

2 Oregon dairy manure digesters cited for air quality violations

https://www.statesmanjournal.com/story/news/2021/12/22/2-oregon-dairy-manure-digesters-cited-air-quality-violations/8985904002/

 Tracy Loew

Salem Statesman Journal

Two Oregon dairy manure digesters, both supported by taxpayers, have been fined a total of $38,201 for violating their air quality permits.

Digesters, which break down manure and other organic material to create energy, are regulated by the Oregon Department of Environmental Quality.

DEQ fined WOF PNW Threemile Project in Boardman $19,500 for exceeding its limit for fine particulate matter emissions.

That happened because the facility was using more natural gas than projected to dry manure for animal bedding.

Fine particulate matter emitted in excess of permit limits can contribute to human health problems including chronic bronchitis, irregular heartbeat, decreased lung function and respiratory distress.

The violation began in June 2019, and continued through September 2020.

WOF PNW leases land from Threemile Canyon Farm and has a manure supply agreement with Columbia River Dairy, which supplies milk to Tillamook Creamery.

It received an Enterprise Zone Tax Abatement which made it exempt from property taxes during construction and for its first seven years of operation. And it received $10 million in tax-exempt financing from Oregon Private Activity Bonds – tax-exempt financing for construction projects that benefit the public.

"Drying manure is an important step in the larger digester project which Threemile Canyon Farms developed to reduce methane discharge and generate a renewable energy source," said Jennifer Maleitzke, director of communications and external affairs for R.D. Offutt Company, which owns Threemile Canyon Farms.

"Threemile takes compliance obligations very seriously. When we were notified in August 2020, we took immediate action and completely fixed the problem by October 2020," she said.

DEQ fined Farm Power Misty Meadow in Tillamook $18,701 for failing to operate a combustion flare, allowing air pollutants including volatile organic compounds and methane to be emitted at uncontrolled rates.

VOCs are ozone precursors that lead to the formation of smog. Methane is a potent greenhouse gas that contributes to climate change.

The violation took place between July 3, 2019 and May 4, 2021. The company also was cited for failing to accurately report flare malfunctions to DEQ, and failing to install a warning signal connected to the flare.

Farm Power operates two digesters, and has a third under construction. In Tillamook County, its digester serves Misty Meadow dairy.

Farm Power received $1 million in cash incentives from Energy Trust of Oregon.

Farm Power Misty Meadow did not respond to interview requests.

The fines were among 18 DEQ levied during October and November, totaling $2.57 million.

Wayne County wetland continues to suffer: Farm with massive hog waste spill nets new violations amid bacteria concerns

https://www.northcarolinahealthnews.org/2023/07/28/wayne-county/

A year after a collapsed digester caused nearly a million gallons of hog waste to escape, investigators found high levels of fecal bacteria in a nearby waterway.

by **Will Atwater**July 28, 2023

This is an aerial photo of White Oak Farm taken by Neuse River Riverkeeper Samantha Krop during a routine surveillance flyover on August 3, 2022. The scene alerted Krop that something was wrong. Credit: Samantha Krop

By Will Atwater

Last August, during a routine surveillance flyover, Samantha Krop spotted something odd at White Oak Farm, a Wayne County biogas and industrial hog farm operation.

“I noticed that the lagoon, which is a covered lagoon, meant to be producing biogas through the anaerobic digestion process, was flattened, and it just looked different,” said Krop, the Sound Rivers Neuse Riverkeeper.

Curious about what she’d seen during the flight, Krop decided to dig through the N.C. Department of Environmental Quality’s records for possible answers.

“We found sort of a treasure trove of documents outlining a major spill that had happened there over Memorial Day weekend,” Krop said.

In May 2022, the owners of White Oak Farm reported to the NCDEQ that nearly a million gallons of hog feces, decomposing hog carcasses and food waste seeped from a failed hog waste “digester” and spread out over surrounding fields. Of the total waste amount, 10,745 gallons also entered the Nahunta Swamp, a “water of the state,” according to an NCDEQ release issued in December of last year.

Accounts differ regarding how much waste flowed from the site into nearby wetlands. In a Sept. 6, 2022 article, the News and Observer reported that a minimum of “37,000 gallons” of hog waste, roughly three times the amount reported by NCDEQ, had reached nearby wetlands.

By the close of 2022, NCDEQ’s Division of Water Resources issued a $34,520 fine to the operators of White Oak Farm “related to a May 2022 waste discharge at an animal operations facility in Wayne County,” according to the agency.

A notice of more infractions

Earlier this month, roughly a year after Krop’s surveillance flyover, NCDEQ sent a letter to B&B Partnership, the owners of White Oak Farm, informing them that the Nahunta wetland is still being affected by runoff from the farm.

Specifically, water sampling tests performed in March and April revealed “high levels of fecal coliform and nutrients in an unnamed tributary to Nahunta Swamp west of the digester at your facility,” according to the letter.

Also spelled out in the letter is that the amount of fecal coliform — the type of bacteria present in feces that can cause illness in humans and

animals — far exceeds the allowed standards during testing that extended over at least a month's time.

'Really terrible science experiment' leads to weeks-long spill from NC hog-waste lagoon

HTTPS://CWFNC.ORG/REALLY-TERRIBLE-SCIENCE-EXPERIMENT-LEADS-TO-WEEKS-LONG-SPILL-FROM-NC-HOG-WASTE-LAGOON-READ-MORE-AT-HTTPS-WWW-NEWSOBSERVER-COM-NEWS-STATE-NORTH-CAROLINA-ARTICLE264779224-HTMLSTOR/

By Adam Wagner, Raleigh News & Observer
September 6, 2022

The state inspector knew immediately there was trouble at White Oak Farms. When she visited the Wayne County farm on Feb. 3, the N.C. Department of Environmental Quality inspector saw a thick layer of hay laden with charcoal-colored foam in a ditch. That foam seemed to have oozed from under a black tarp covering a hog waste lagoon where manure was combined with unusual ingredients like liquified hog carcasses and discarded hot dogs and deli meat in a slurry to generate methane. The farm's owners, including a former member of the National Pork Board, had not reported a spill.

In a notice of violation dated Feb. 18, two weeks after the inspection, David May, a supervisor in DEQ's Washington Regional Office, wrote that the inspector couldn't tell how deep the foam was. But, May wrote, "the inspector stepped in that area sinking at least 4 inches on the edge." White Oak Farms' problems were just beginning.

Four months later, on May 30, the black cover ruptured, sending an estimated three million gallons of the gelatinous gray foam across the farm and toward nearby Nahunta Swamp. By the time the spill ended weeks later, enough foam had spilled to fill more than four Olympic-sized swimming pools. At least 37,000 gallons had reached wetlands.

An anaerobic digester on White Oak Farms in Fremont, N.C., tore on May 30, sending foam across the property. N.C. Department of Environmental Quality Environmental advocates learned about the spill by chance. They are outraged that it happened with minimal public notice, particularly considering that DEQ staff were monitoring the spill even as the department was finalizing a permit making it easier for anaerobic digesters to get environmental approval and easier for farmers to install them.

Riverkeepers argue that DEQ's regulation of White Oak Farms shows the department is not prepared for a potentially exponential increase of digesters on North Carolina's hog farms. They learned about the White Oaks Farms spill on Aug. 3, more than two months after it began, when Sound Rivers' Neuse Riverkeeper Samantha Krop flew over the facility. Krop saw that the black bubble that was supposed to be capturing gas appeared deflated, with water pooled across its surface. Krop also noticed that there was no vegetation around the lagoon and that it looked like dirt had been moved around southeast of the digester, where the property borders Nahunta Swamp.

"It just didn't look right," Krop said. "It didn't look like they were functioning properly."

An anaerobic digester on White Oak Farms in Fremont, N.C., split open in late May, sending foam oozing out for at least three weeks. Shown here on August 3, the farm mixed hog waste with deli meat, hot dogs and liquified pig carcasses to generate methane in the digester.

The Feb. 3 inspection focused on the covered lagoon, a system called an anaerobic digester. Farmers pump manure and other unwanted material into the lagoon, where it decomposes, releasing methane and other gases. Digesters capture those gases, particularly methane, and use them to produce electricity or purified natural gas. In recent years, agricultural groups and environmentalists have debated the use of anaerobic digesters in North Carolina.

These disagreements played out first against the backdrop of the 2021 Farm Act, which ordered the N.C. Department of Environmental Quality to write a general permit allowing most future digesters to move quickly through the environmental approval process. The N.C. Pork Council and other agricultural interests argue that covering waste lagoons reduces odor and prevents emissions of methane, a potent greenhouse gas. They also offer farmers a revenue stream.

In a written statement, Roy Lee Lindsey, the Pork Council's CEO, said, "Digesters are a safe and proven technology that provide significant environmental benefits. While this situation was unfortunate, it is an isolated incident and should not discourage us from continuing to pursue renewable natural gas projects in North Carolina." Environmental groups argue that digesters effectively lock in what they call a primitive waste management system in which hog manure and urine are washed into lagoons before being sprayed across nearby fields.

The White Oak Farms spill demonstrates the risks digesters pose, said Blakely Hildebrand, a senior attorney at the Southern Environmental Law Center. "It goes to show that these digester systems aren't the environmental, climate silver bullet that the hog industry has painted them to be," Hildebrand said. DEQ issued the general permit on June 30 — a week after inspectors concluded the White Oaks spill was continuing. As they finalized the permit, DEQ officials never revealed publicly that staff had been monitoring an active digester spill.

That general permit would not have covered White Oak Farms' digester. It only covers systems that process hog manure and urine, said Anna Gurney, a DEQ spokeswoman, not those that add other things into the slurry like White Oak Farms' liquid pig carcasses, cast-off hot dogs and deli meat. Despite the digester debate, almost nobody knew a North Carolina hog operation was already operating by adding hogs and meat products to the manure under its black plastic balloon.

"We have never heard of this before. We started asking around and nobody else in the environmental advocate world that we're in has heard of this, either," Jill Howell, the Pamlico-Tar riverkeeper, told The News & Observer. Howell continued, "It just all seems very strange and like one really terrible science experiment." A N.C. Department of Environmental Quality inspector holds a handful of the foam that

spilled May 30 from an anaerobic digester on White Oak Farms in Fremont, N.C. The farm was mixing hog manure, slurry made from dead hogs and cast-off deli meat in the digester to generate methane.

'THIS IS THE ULTIMATE RECYCLING'

Deborah and Todd Ballance started hog farming in 1990, first as contract growers. When Coharie Hog Farm folded in 2009, the Ballances bought the pigs on their farm and went independent. "Since the farm was built by my husband's grandfather our family has always strived to look to the future in order to do what is best for our family, our animals, our community, and our environment," Deborah Ballance wrote in an email to The News & Observer.

"We believe strongly in being sustainable and that is why we covered our lagoon and captured the methane for electricity."

The N.C. Pork Report, a N.C. Pork Council trade publication, profiled the Ballance family in 2017, shortly after then-U.S. Agriculture Secretary Sonny Perdue named Deborah Ballance to the National Pork Board. The story says Deborah and Todd met in first grade and farm land passed down by Todd's grandfather. It also discusses the possibilities their efforts to turn manure into energy offer. Deborah Ballance told the Pork Report, "I think we basically reinvent ourselves every three years. You need to keep your ear to the ground and see what you need to be doing next or thinking about next, and that's what we try to do."

The Ballance family had long been exploring how to generate revenue from hog waste, according to decades of permitting documents reviewed by The News & Observer. In 1997, White Oak Farms sought and received a permit for a two-lagoon system that it said would help lower nitrogen levels before the waste was sprayed over nearby fields. The farm planned to keep hog manure from reaching the lagoon and spread it on a field. Evaluations were underway, the permit said, of compacting solid waste and using it as animal feed.

A 1997 application said, "White Oak Farms is very confident that the waste will become suitable animal feed. When it is converted to animal feed it will no longer be land applied." In 2002, the farm said the manure capture system hadn't worked as advertised and the equipment used to move liquid between lagoons had proven noisy and expensive to operate. At that point, the farm was permitted to have 5,500 sows.

They wanted more hogs, but were limited by a moratorium on new or expanded hog operations the N.C. General Assembly made permanent in 2007 — a moratorium rooted in The News & Observer's Pulitzer Prize-winning "Boss Hog" series that showed how a lack of regulation around the industry was leading to environmental threats near some farms. Another 2007 bill offered a solution.

The Renewable Energy and Energy Efficiency Portfolio Standard supported renewable energy in North Carolina. It also required that 0.2% of the state's energy come from swine waste by 2018. In 2013, White Oaks Farms asked DEQ: Could it add 60,000 hogs as long as it added an anaerobic digester, controlling odor, groundwater contamination and other environmental impacts?

"Despite a moratorium in place in North Carolina on new hog farm construction, we found the ideal way to expand with finishing floors. We could build a methane digester and sell power to the power company," the Ballance family wrote in a 2017 USDA loan application. Electricity generated by White Oak Farms could power about 3,000 homes on Duke Energy's grid, according to the application. "We will take our hog waste and mortality and use it as fuel!

This is the ultimate recycling," the Ballances wrote. DEQ approved the permit in October 2013. In later permits, the regulatory agency would require the Ballances to expand in phases, starting with 15,000

hogs Hildebrand questions DEQ's approval, pointing to a rule that any waste management system for a new or expanded hog farm must have a synthetic liner preventing contaminants from seeping into soil or groundwater.

The permit approved by DEQ in 2013 and again in 2017 says the 8.75-million gallon anaerobic digester is "earthen-lined." "It's a very prescriptive standard," Hildebrand said. "These performance standards aren't vague." The digester started operating in April 2019.

Randy Wheeless, a Duke Energy spokesman, said the utility has bought power from White Oak Farms since 2019. Over that period, it has averaged enough electricity to power about 400 homes. Energy generated by hog waste, Wheeless said, is more expensive than energy from solar farms or natural gas. Wheeless said, "It's a premium product because there's just not that many facilities in a position to do that, and you still have a law in place in the state that says utilities shall buy or secure that type of power."

CHANGING SOURCES

In 2020, DEQ approved an updated permit limiting what could go into the digester each day. The farm could add swine waste, up to 20,000 pounds of food waste like hot dogs or deli meat from Smithfield's Kinston plant, and 210,000 pounds of dead pigs. With that approval, the farm started adding the dead pigs in July 2020.

They later reported the pigs caused significantly higher methane production. Around the same time, the COVID-19 pandemic was impacting the farm's operation. Despite having permission to add as many as 15,000 hogs, the farm instead found itself operating with 100 sows at most.

That impacted the digester, too. In a year-end report, the Ballances wrote, "With swine production and processing decreasing industrywide, the facility has experienced a temporary change from a manure dominated digester feed source to primarily a food waste and mortality source." In other words, the farm was putting more dead pigs and cast-off meat into the digester than hog waste, despite its permit explicitly stating that manure should be the main additive.

The trend continued throughout 2021, with the number of hogs dwindling from 81 to 50. Still, the digester was operating well on mostly dead pigs and unwanted meat. In 2021's year-end report, the Ballance family wrote, "From an energy production standpoint, the facility experienced its best period to date."

The farm submitted that report on Jan. 31, 2022. Three days later, the DEQ inspector found signs of the digester's unreported spill. During a February inspection, a N.C. Department of Environmental Quality inspector found signs that a discharge of foam from an anaerobic digester on White Oak Farms had not been reported. Those signs included foam on top of the digester. N.C. Department of Environmental Quality

THE SPILL

The bubble burst in the middle of the night. White Oak Farms' digester ruptured around 3 a.m. on May 30, according to a press release the farm sent to local newspapers. Later, the farm would write that "an unexpectedly severe digester foaming event" started with a fissure on the northern face of the black plastic covering.

That's also where the DEQ inspector identified the previous, unreported spill during her February inspection. A "thick foam" made of hog matter, liquid and gases gurgled out of the digester. According to the farm's accounts, the foam ran across a field and reached a forest that contains wetlands.

The farm maintains none of the foam reached Nahunta Swamp on its southern boundary. DEQ staff conducted several inspections over the ensuing weeks. On June 3, they saw foam on nearby surface water, possibly including Nahunta Swamp. That foam was cleaned up when staff returned on June 7. The spill was still active on June 23, according to a notice of violation DEQ issued in July.

That notice said DEQ staff had detected "objectionable" odors and air quality and saw foam coming out of concrete structures on the digester's western edge. The covering on a Wayne County lagoon broke open in late May, sending more than four swimming pools' of foam across White Oak Farms in Fremont. The damaged anaerobic digester is shown here on August 3. Samantha Krop Sound Rivers What caused the spill is not immediately clear, and the Ballance family did not directly answer an emailed question about why the digester failed.

But an N.C. State professor who studies anaerobic digesters said the dead hogs and cast-off meat could have played a role. Adding materials containing fat, oil and grease to anaerobic digesters can significantly heighten biogas production, Mahmoud Sharara wrote in an email to The News & Observer. But at the same time, long chain fatty acids within the so-called FOG material can cause a layer of foam and crust to develop on top of the slurry. Sharara, an agricultural and biological engineering professor, does not have first-hand knowledge of the White Oak Farms facility.

It is possible, Sharara added, that the higher levels of gas could have been incompatible with existing infrastructure like the generator or motor that processed the gas. Pressure could have built up underneath the cover, he wrote, ultimately causing the rupture and allowing the foam to spill out.

In response to The News & Observer, the Ballance family wrote, "As soon as our cover tore and leaked foam, we called the Department of Environmental Quality and began immediate cleanup. We have repaired our cover and complied with every requirement and suggestion made by DEQ. We will continue to consult with our engineer and scientific consultants to perfect our unique operation." As of June 13, there were no hogs on White Oak Farms.

LINGERING QUESTIONS

After learning of the spill via Krop's flight, riverkeepers dug into the permit record. They were alarmed that they hadn't heard of the spill before and that the public notice requirements allowed White Oak Farms to report the spill without specific details. "There was no reference to what was in the wastewater foam, there was no acknowledgment that it was swine waste or dead hogs or food waste product," Howell said.

"It's like a bare, bare bones public notice."

North Carolina laws require any facility that spills more than 15,000 gallons of animal waste into the state's surface waters or wetlands to issue a press release in both the county where the spill happened and the county immediately downstream. That press release needs to say where and when the spill happened, how much waste was discharged, how long the spill went on and what the facility is doing to prevent further spills.

Hildebrand, of the Southern Environmental Law Center, said White Oak Farms followed the law, but that the law or DEQ should require information about a spill to be spread futher than a public notice in a local newspaper's classified section.

"Especially in this day and age. I think the law could be better, the requirements could and should be better around public notification," Hildebrand said, adding that DEQ is able to issue public notification itself or require operators that have spills to issue more widespread notification.

Advocates also wonder whether DEQ can adequately regulate digesters, particularly considering Dominion Energy and Smithfield's joint $500 million Align RNG initiative that is already forging ahead in Duplin and Sampson counties. With more digesters appearing likely to come online in the coming years, Howell and other advocates are concerned that DEQ field staff have not been specifically trained to inspect them. Gurney, the DEQ spokesman, said the Division of Water Resources "will conduct additional training for regional inspectors as needed as facilities are covered by the Digester General Permit."

The department's field staff noted violations at White Oak Farms and issued notices of violation, including the one in February, but Howell argues that wasn't enough to convince the farm to correct the problems. "DEQ's enforcement was insufficient in all of this," Howell said. On July 5, DEQ issued another notice of violation against White Oak Farms. The department said the Ballance family's improper operation of the digester had resulted in the spill and impacts on nearby surface waters and wetlands.

The state agency said the farm had failed to update its permit to account for operating without hogs for months and had on multiple occasions accepted more than 20,000 pounds of food waste on a given day, exceeding the amounts allowed in its permit. It noted that ammonia levels in wells between the digester and Nahunta Swamp were more than 12 times higher than the allowable concentration. In response to DEQ, the Ballance family said they stopped adding new material to the digester "at least three weeks" before the spill happened.

The Ballance family also mentioned its plans to build another digester. Ideally, they wrote, the manure and meat products that had spilled from the old digester could be pumped into the new one to "seed the digestion process." The new digester would have a synthetic liner to protect groundwater, as well as a berm on its southern side to contain any future spills.

Renergy ordered to close biodigester facility in Greene County

https://www.daytondailynews.com/local/renergy-ordered-to-close-waste-treatment-facility-in-greene-county/O6K77YDFH5GNLFALIX4NH7OO54/

LOCAL NEWS

By Kristen Spicker and London Bishop

Updated Sept 20, 2023

X

After years of citizen complaints and EPA violations, the Dovetail biodigester in Greene County will be shut down, potentially bringing an end to a decade-long fight between parent company Renergy and the surrounding community.

Renergy agreed to shut down the digester facility, Ohio Attorney General Dave Yost announced Wednesday.

The shutdown comes at the end of a particularly smelly summer, local residents say.

“It has been so bad,” Gary Goldblatt, who lives nearby, said of the smell Wednesday. “Especially on cool, kind of humid nights we’ve had for the last week or two. Around 9 at night, it hits you like a brick to the face. Last night it was 7:30 we had to close all our windows and literally it has not gone away. It smelled all day today.”

“Renergy’s shutdown will eliminate both the environmental problems in this case and the olfactory nuisance that the site has become,” he said. “I am asking the court to approve our proposed order so Renergy can move swiftly and properly with a safe cleanup.”

ExploreRELATED: Ohio EPA seeks legal action against Dovetail, Renergy over biodigester pollution

The state also requested a final judgement in Greene County Common Pleas Court, asking the court to require Renergy to:

- Stop accepting feedstock and waste by Oct. 1
- Empty the digestate storage tank by Dec. 15
- Empty and clean the digester and other equipment by Jan. 15
- Submit documentation of the emptying and cleaning by Jan. 30
- Request termination of permits and certify that the facility is permanently shut down by Jan. 31

The filing also seeks an additional $25,000 fee in penalties, bringing the total penalty to $100,000.

“We want to make sure the Attorney General holds their feet to the fire,” Goldblatt said.

Jude Eschete, who lives in the Waterford Landing neighborhood, moved into his home with his wife in August of last year, and said he could tell almost immediately something was off. Eschete, a Marine veteran and engineer, moved to Fairborn from Louisiana for work.

“I started posting in our neighborhood group, and I was like ‘What is that? What am I smelling?” he said. “And why, in that entire nine-month period (prior) when we were building our house, were we not told about this?”

With a deadline for the facility shutting down set for the end of January, Eschete said he is looking forward to being able to enjoy his property again.

“We were always sitting on our back porch in Louisiana, and coming up here it was such a shame we couldn’t enjoy our time outside,” he said. “We couldn’t have people over. It was embarrassing.”

The Greene County facility is one of two Renergy digesters in the state. The second facility is in Morrow County. The digesters use bacteria to break down manure and other organic materials, eventually turning them into methane which is sold for electricity production, according to Yost's office.

The state previously sued Renergy on behalf of the Ohio EPA for air and water pollution violations at both digester sites.

Yost said the air pollution violations were addressed, but water pollution violations have continued, along with complaints about the odor.

Manure spill splashes 300,000 gallons near Tillamook Bay

- Updated: Jul. 23, 2019, 6:20 p.m.|
- Published: Jul. 23, 2019, 5:12 p.m.

A cloudy winter day at Tillamook Bay on the Oregon coast. Jamie Hale/The Oregonian

- **Shane Dixon Kavanaugh | The Oregonian/OregonLive**

A massive manure spill at the Port of Tillamook Bay discharged roughly 300,000 gallons of treated liquid excrement into the area, some of it reaching waterways mere miles from the ocean.

Oregon state officials have yet to shut down Tillamook Bay or impose restrictions on commercial and recreational shellfish harvesting, as they've done during prior manure mishaps.
The state's Department of Environmental Quality and Department of Agriculture are analyzing water samples from the bay and from around the spill site, including Anderson Creek, a tributary of the Tillamook River.

They expect to have preliminary results by Wednesday morning, said Lauren Wirtis, a spokeswoman for the environmental agency.

The manure had been held in an anaerobic digester tank, which breaks down dung into biogas that can be used for electricity and fertilizer for farms and agriculture.

The process creates a waste with fewer pathogens. That, in turn, makes it far less harmful than raw sewage, Wirtis said.

It's not yet clear how or when exactly the spill occurred, said Michele Bradley, the Port of Tillamook Bay's general manager. Port workers discovered the spill Monday morning and contacted state authorities, she said.

Some of the waste entered the port's stormwater system, which empties into a section of Anderson Creek about 2 ½ miles from the Tillamook River.

Regenis, a tenant of the port that operates the manure digester, could not be reached for comment.

State officials in 2017 temporarily closed Tillamook Bay after a nearby spill caused more than 190,000 gallons of manure to enter the water.

Tony Silveria Dairy, which operated the faulty manure tanks, was later fined nearly $17,000.

Multiple agencies react to manure spill at Port's digester operation

https://www.tillamookheadlightherald.com/news_paid/multiple-agencies-react-to-manure-spill-at-port-s-digester-operation/article_be4c4c40-b3b5-11e9-be0f-d3c4f211c14f.html

On Monday, July 22 the Oregon Department of Environmental Quality (DEQ) and the Oregon Department of Agriculture (ODA) received notification from the Oregon Emergency Response System (OERS) that a release occurred from the Regenisis anaerobic digester, at the Port of Tillamook Bay. First Strike Environmental responded and has been on site since noon on July 22.

According to a release from DEQ, upon further investigation, it was discovered that approximately 300,000 gallons of partially digested manure, digestate, was released and travelled from the digester to Anderson Creek. There is a 4-foot berm surrounding the digester with two entrances. According to Andrea Cantu-Schomus, Director of Communications for the ODA, the Port of Tillamook Bay bulldozed the entrances closed to contain the digestate.

According to Michele Bradley, General Manager of the Port of Tillamook Bay (POTB), "the bulk of the manure was contained on the digesters," she told the Headlight Herald. "Manure that was at the digester made it into the system – the POTB does not know how much, but there was 6 inches of standing manure in portions of the digester slab area that was then pushed and recycled into the digester, lessening the impact of what might have made it into the stormwater system."

Bradley could not confirm how much that may have been.

"The POTB does not have a total gallon number on what might have made it into the stormwater system," she said. "It was tank two, which is a finishing tank of the bay. The manure came from an overflow tank after a technical malfunction. The Port is almost 6 miles via waterway to Tillamook bay. It is not a source of drinking water."

The POTB is the owner of the tank and is responsible for the Stormwater system via a DEQ General Permit, so it is in charge of all stormwater discharge within the industrial park.

"There has been testing from the DEQ, ODA, and Oregon Fish and Wildlife, among others," Bradley said. "A vacuum truck was brought to the location and has been sucking water out of the bay. The POTB doesn't know the impact of the downstream yet but DEQ tested on Tuesday, July 23."

The POTB's stormwater system was built by the Navy when they built the Naval Air Station for WWII. It includes groundwater as well. The Port has a settling pond near the outfall and before Highway 101 that holds millions of gallons of water. From there, it travels under the highway via Anderson Creek, joins with South Prairie Creek, and enters the Tillamook River, then into Tillamook Bay.

"DEQ and ODA have taken and will continue to take samples from various locations in and around the site. The analysis of the samples is expected soon," Cantu-Schomus said. "Because the material is digestate and now raw sewage, there are no restrictions for shellfish operators or recreational harvesters in Tillamook Bay at this time." As sampling results are completed, ODA will decide whether to issue any restrictions. ODA has reached out to all produces in the area to share information about the release of the digestate.

According to the release, results of water samples taken from Tillamook Bay indicate there was no impact on water quality in the bay from the release of treated manure waste at the Regenis facility. As a result, analysts with the Oregon Department of Agriculture shellfish and food safety programs have determined that the release does not pose a health risk and no action is required by shellfish harvesters.

Water samples taken from the Regenis outfall pipe at Anderson Creek did show elevated levels of e coli, but downstream tests did not show elevated e coli levels. The Oregon Department of Environmental Quality is working with the Port of Tillamook Bay on ways to further contain the contaminated water at the outfall.

The ODA will continue to monitor water quality in the bay by taking additional samples and testing for potential contamination.

More than 18,000 cows are dead after dairy farm explosion in Texas Panhandle

---

LUBBOCK — More than 18,000 cows died and one farm worker is in critical condition following a dairy farm fire in the Texas Panhandle.

The fire started Monday night at South Fork Dairy Farm in Dimmitt, about 66 miles south of Amarillo. The Castro County sheriff's office, along with fire departments from Dimmitt, Hart and Nazareth, were the first responders to the explosion in the small town of nearly 4,200, according to the sheriff's office.

One person was trapped inside the dairy farm but was rescued by first responders, according to the sheriff's office. They were later flown to a Lubbock hospital.

According to the Animal Welfare Institute, the incident is the deadliest fire involving cows in nearly a decade. A statement provided by the Texas Association of Dairymen on behalf of the dairy industry expressed condolences for the incident.

"We are deeply saddened for the family dairy, and everyone affected by the tragedy that occurred at South Fork Dairy farm," the statement said. "The cause of the fire is still under investigation, and we are deferring to the appropriate authorities to make that determination."

In 2019, Texas authorized the facility to more than double the number of cattle allowed on-site from 11,500 to up to 32,000, according to a permit with the Texas Commission on Environmental Quality.

The state also authorized the facility to increase its manure production by more than 50% in that expanded permit.

Wastewater from the facility drains into the Brazos River Basin.

In a statement, TCEQ spokesperson Victoria Cann said that the agency will ensure that dead livestock and debris are disposed of properly. She said the agency is not aware of any environmental impacts from the explosion.

Castro County is the second-highest milk-producing county in the state and has more than 59,361 cows. According to a United States Department of Agriculture report, the county produced more than 147 million pounds of milk in February.

Texas Agriculture Commissioner Sid Miller called the incident devastating but said he was grateful there were no further injuries to workers or loss of human life. He also called for the findings of the investigation to be made public once it is finished.

"This was the deadliest barn fire for cattle in Texas history and the investigation and cleanup may take some time," Miller said. "There are lessons to be learned and the impact of this fire may influence the immediate area and the industry itself. Once we know the cause and the facts surrounding this tragedy, we will make sure the public is fully informed — so tragedies like this can be avoided in the future."

The 18,000 cows killed represent just a fraction of the 625,000 dairy cows in Texas. Including beef cows, there are 13 million in the state, according to the Texas Almanac. Large amounts of cattle have died in Texas before. During Winter Storm Goliath in 2015, 35,000 cattle froze to death.

The state fire marshal's office is conducting an investigation into the cause of the fire.

Methane fueled explosion at Aumsville dairy farm causes fire

https://www.oregonlive.com/pacific-northwest-news/2012/07/methane_fueled_explosion_at_au.html

- **Joseph Fanelli, The Oregonian**

An explosion from a methane leak at an Aumsville dairy farm led to a fire Wednesday afternoon.

Betty Bielenberg, co-owner of Oakley Farms at 11314 Mill Creek Road, said the explosion happened after the rubber top of a methane digester expanded and began to release methane around 12:30 p.m. She said the methane" caught a spark," resulting in an explosion and then fire on the original tank and a second methane digester.

A methane digester is a large tank that uses methane from cow manure to produce clean energy.

Bielenberg said no people or animals were hurt and that the fire was "mostly out" by the time Aumsville fire officials arrived.

She said no other structures at the dairy farm were damaged.

KGW television released video of the explosion.

Explosion Rocks US, More Than 10,000 Evacuating

Story by Andrew Sanders • 1mo

https://www.msn.com/en-us/news/world/explosion-rocks-us-more-than-10000-evacuating/ar-AA1ioXhl

A gas pipeline explosion in Middleton, Idaho led to an evacuation of the town.

The explosion occurred after a worker ruptured a 22-inch pipeline with an excavator.

The gas line was turned off within 20 minutes and residents within a 4-mile evacuation zone were asked to shelter in place.

The town of roughly 10,600 people was ordered to evacuate.

Canyon County officials announced, “The gas company is taking over the investigation.”

“There was no ignition, fire, or explosion associated with this incident and the cause is under investigation,” the Williams Companies, a natural gas distributor that owns the pipeline, told the AP.

Chief David Jones of the Middleton Fire Department said, “It was a pretty substantial explosion just due to the pressure in that line.”

“The explosion was felt,” Jones added, “and the gas flow could be felt about a mile away.”

The evacuation orders were lifted later in the day and the area was declared safe.

The gas company denied that there was an explosion, but local residents reported hearing an explosion and a noise resembling low-flying jets.

The cause of the incident is under investigation.

Re: Public Disclosure Request dated December 4, 2023, regarding Pacific Ag/Sunnyside RNG proposed bio-digesters in Yakima County.

Dear Ms. Mendoza:

Yakima Emergency Services has received your email for a Public Disclosure Request dated December 4, 2023, requesting copies of all correspondence between Yakima Emergency Services and Pacific Ag/Sunnyside RNG regarding the proposed bio-digesters in Yakima County, including copies of discussions related to concerns regarding the potential for fires and explosions. Additionally, you request responses to questions A through P as outlined in your public records request.

Yakima Emergency Services has completed its search for records responding to your December 4, 2023, public records request. Our office does not possess any correspondence or discussions regarding Pacific Ag/Sunnyside RNG's proposed bio-digesters in Yakima County. After reviewing your request, the information you are requesting falls outside of the scope of Yakima Emergency Services. Below please find contacts that may be able to provide you with the information for your public records request and/or answers to your questions.

Below please find responses to your questions outlined in your public records request:

A. What is the volume of each tank? Not applicable
B. How long does it take to fill a tank? Not applicable
C. How long does it take to empty a malfunctioning tank? Not applicable
D. How would Sunnyside RNG dispose of the tank contents in a situation where the wrong microbes are growing? Not applicable
E. What can go wrong? Not applicable

F. Are there potential chemical and biological processes that might produce gases other than carbon dioxide and methane? Not applicable
G. Please name all the desired microbes that do the work inside the tanks. Not applicable
H. Please name all the undesired microbes that might interfere with digestion. Not applicable
I. Is there a potential for increased pressure inside a tank due to production of undesired gases? Not applicable
J. What is Sunnyside RNG's emergency plan in case of a tank explosion? Not applicable
K. Do emergency plans include a protocol for evacuating neighbors? Not applicable
L. What is the maximum potential range of aerial distribution of materials from a tank in the event of an explosion? Not applicable
M. Please describe protective measures for emergency management personnel assigned to combat fires and explosions at the digester. Not applicable
N. What is the expected life of a digester tank? Of pipes that transport methane, manure, and other digester components? Not applicable
O. Does the Sunnyside RNG digester include add-ons that capture and process excess ammonia, hydrogen sulfide, and phosphorous? Not applicable
P. How will Sunnyside RNG manage ammonia and hydrogen sulfide that is produced by digestion? Not applicable

In your request you have requested that if our agency does not maintain any public records, to advise you of who does and include the proper custodian's name and address.

Sunnyside Residents
Notice of Public Comment on 60-Acre BioMethane Plant
Thursday, November 30, 2023
5:30 pm @ Gusto Casa Mia 200 N 1st St Sunnyside

The City of Sunnyside and the Port of Sunnyside announced it has entered into a public comment period on the proposed BioMethane Plant/Digester project and residents may voice any concerns about the economic and environmental impact the project may have. The plant would use anaerobic digesters to process local manure and agricultural waste to create natural gas. We can assist you to enter your public comment to the city and port. If you have questions or concerns, join us for this community meeting about the Pacific Ag project.

- Learn more about what a biomethane digester is.
- What are the water and air quality risks?
- Why is it being built next to a residential area?
- Why hasn't an environmental impact statement been released?
- What is the possibility of a plant explosion? As has happened in other locations.
- Why hasn't any information been provided in Spanish to Spanish-speaking residents?

Public comments must be submitted to Trevor Martin, Community & Economic Development Director, at tmartin@sunnyside-wa.gov by December 5th.

For more information about this community meeting, call Maria with ELLA at 509-506-0013, or email at Maria@WeAreELLA.org.

The Port of Sunnyside human waste water treatment plant is pretty smelly and everyone gets by just fine- and it's in a residential area as well. We need projects like these to solve solutions like using a sustainable resource and turning it into energy. Literally a win win plus creating jobs. Places like this would be heavily up to code on safety and environmental impact because it's funded by taxpayers.

1w Like Reply 12

Chela N. Licona
They can find a different location. This is too close to many of our homes and as it is the mushroom plant with its "state of the art facility" has significantly impacted our quality of life b/c the air quality and smell are much worse than any bad air prior to its existence. I prefer they build it far away from our homes or in their neighborhood. We do not need projects that harm our health and quality of life.

Chela N. Licona
This issue isn't as simple as "getting by just fine" by putting up with yet another stench caused by a project that "will generate jobs" and is for the greater good. Those of us who are against the plant are not against the Port or economic development in our community. We can want better for our community and still disagree with the Port of Sunnyside and County. We can want better for our community and still find it unconscionable that there is no environmental impact statement despite requests for one. Many of us have lived in the area or close to the site for generations, and we have been directly impacted by the Port and the County's shortcomings in the past. Many of us have trusted (hoped) that things would come out as the Port or the County has promised and now live with the consequences (contaminated water, worse air quality, etc.). There are other options: The Port can find another location far away from our

M'Liss Bierlink
Brittany Byma The Port of Sunnyside DOES NOT have a human waste facility. It's industrial waste water only. I worked there for 11 years and know 100% they treat only industrial waste water.

1w Like Reply 2

Brittany Byma
M'Liss Bierlink Thank you for clarifying. Living next to it for 20+ years, I thought it was because of the smell. Still deal with it daily but I don't complain because I know it's for the better of our community. The Port of Sunnyside does great things for all of us that we don't even realize.

On the pacific ag website they break down what they are doing in Sunnyside. It looks like it helps the farmers, gets jobs for the people, and eliminates waste that would flow back into the water systems via runoff. Not saying it's perfect but there are pros and cons

Toni Soto Yes, Arnold Martin is a Port Commissioner. He and the other commissioners should be forthcoming about the environmental impact of this biomethane plant. This Oregon digester corporation, Pacific Ag, is getting over $12 million in our WA state taxpayer dollars for the infrastructure development of this proposed industrial site. Examples of what has happened in other communities with biomethane plants.

Teodora Nancy Martinez
My concern is the traffic this is going to create. The cow waste will be trucked in and with over 30 diaries possibly contracting with them that's a lot of crap being moved. The emissions alone from the trucks is going to cause issues! Plus what are they going to do with the waste water after they are done with their process, dump it where?

1w Like Reply 2

Tina Coder-Guy several people have asked the city and the port exactly those questions about the transportation of manure and how Pacific Ag will prevent possible leakage and spills on the roadway. We still have no answers to any of those questions. They are anticipating at least 140 transported manure loads PER DAY, and we don't know how Pacific Ag will prevent or mitigate possible spills during transportation.

Re: Public Comment for Proposed Bio Methane Plant/Digesters, Sunnyside RNG and Request for Environmental Impact Statement SEPA-20225.022 WADOE SEPA#202303037

I am writing during this public comment period about the biomethane plant, Sunnyside RNG, proposed for a location near Sunnyside city limits and residential areas. I have obtained some information about biomethane plants in other cities, and I have concerns about any environmental impact risks, particularly with our air and water quality.

I have not seen the City of Sunnyside or Port of Sunnyside address any aspects of potential harm, which I find disturbing given that a simple internet search of biomethane plants and digesters in other cities provides article after article demonstrating that biodigesters have caused some harm in their respective areas, including significant air pollution, water contamination, and even plant explosions causing area resident evacuations.

With the abundant information available from credible sources about the risks associated with biomethane plants, I do not understand how you came to a mitigated determination of non-significance, through your own SEPA review. I need to better understand your qualifications to conduct a thorough and impartial review. It seems to me that if the City of Sunnyside is the lead in the development of this project, designating significant city funding to the project, it appears to be a conflict of interest for you to conduct the SEPA review. A SEPA review of this type of project must be conducted by an outside agency to objectively examine the potential environmental and human impact.

The city and port must also consider the cumulative impact of this project with other issues already affecting the local environment and residents. For example, many of the local dairies, particularly in the Outlook area, are responsible for contaminating the well water of Outlook residents, and are responsible for trucking in water to residents, regularly testing and monitoring resident wells, and provide water filtration systems to residents. There was also a recent explosion and chemical fire at Nutrien Ag Solutions fertilizer plant, and area residents needed to be evacuated because of harmful

chemical gasses released into the air by the explosion. We also deal with unusually high rates of asthma associated with poor air quality. These are just a few verifiable problems affecting residents and the development of a biomethane plant in the same area seems to me, would only exacerbate the health and environmental problems we are already experiencing.

I also find it concerning that the city and port provided no communications in Spanish about the proposed biomethane plant to residents. As you already know, Sunnyside is 87% Latin@, with 70% of these Latin@ families speaking primarily Spanish in the home. There is no other reason for not communicating with Spanish-speaking residents except deliberate exclusion of their opinions and participation within city developments and processes.

The ELLA team canvassed around the area where the biomethane project is proposed, and of the almost 250 homes we visited, we only encountered five families that knew about the project. The few families that were aware of the project spoke only English. None (0) of the Spanish-speaking families we spoke with were aware of the biomethane plant. Once they became aware of the project, they were very concerned about the potential risks to their health, the environment, their property values, and the safety of children that stand near the Sunnyside Mabton Rd to wait for their school bus in the morning.

We also held a community forum on November 30th about this project so that residents had an opportunity to learn more about the project. We invited you, the city manager and council members to attend and none of you showed any interest in attending the event to answer any questions, respond to any concerns, or even listen to residents. It is extremely disappointing that not one city official or administrator could be bothered to attend, especially during a public comment period about the project.

I would like more information about any potential adverse environmental and public health risks. Please provide me with an environmental impact statement based on an objective third party SEPA review. As a concerned citizen, I would expect for city and port officials and administrators to be clear and transparent with their community about any project as significant as a biomethane plant so that we may become familiar with both the benefits and disadvantages of such a project. Communications about the environmental impact must also be provided in Spanish because our community is made up of a significant number of families that primarily speak Spanish.

I have included articles that have me concerned about biomethane plants. I have also included video of the community forum where residents expressed their concerns and screenshots of discussions about the Sunnyside RNG project on Facebook What's Up Sunnyside. Without a thorough and impartial SEPA conducted by a third-party reviewer, or EIS, it is difficult to come to any other conclusion about biomethane plants than what we find online.

I look forward to the City and Port of Sunnyside providing the environmental impact statement for the Sunnyside RNG project for resident's review and additional public comment.

Re: Public Comment for Proposed Bio Methane Plant/Digesters, Sunnyside RNG and Request for Environmental Impact Statement SEPA-20225.022 & 2022.0200, WADOE SEPA RECORD NUMBERS#202303037 & 202305593

Mr. Martin,

We have a received a few comments from residents in Mabton. They are also concerned about any possible adverse effects to the environment and their health with the Sunnyside RNG project. Both Elida Macias and Margarita Fonseca are requesting information about the Sunnyside RNG biomethane/digester plant. As you already know, Mabton residents are dealing with water quality issues and many residents have shared their concerns about how this biomethane plant may exacerbate existing water quality issues.

I have attached their recorded comments to this email. I trust that you have in-house translators to transcribe the recordings. It would be prudent to address these concerns directly with both Sunnyside and Mabton residents. They have valid concerns, and the City of Sunnyside must be willing to speak with residents, including Spanish-speaking residents, most of whom are just now learning about this project. And it doesn't help that the public comment period has taken place during the holiday when most people are honoring their cultural and religious customs, therefore distracted.

We will follow up with you on your next steps with this project. Please let me know if you have any questions about the recordings.

Subject: RE: Comments re: SEPA-2022.0200, Sunnyside RNG LLC

Mr. Martin,

In case the previous emails did not go through, attached again are our comments. Exhibits cited in the comments are available at this link: https://we.tl/t-gXaWvI9h7f.

The link is good until December 12, 2023.

Sincerely,

Amy van Saun
Senior Attorney
Center for Food Safety

Re: City of Sunnyside MDNS issued for City File Number SEPA#2023-0200

Trevor Martin, SEPA Responsible Official
City of Sunnyside
Office of Community Development
818 E. Edison Ave.
Sunnyside, WA 98944

Mr. Martin & The City of Sunnyside:

Please accept these comments on behalf of Center for Food Safety's members in the Lower Yakima Valley and specifically Sunnyside. In addition to these comments, CFS joins the comments of Friends of Toppenish Creek, including all comments regarding the proposed factory farm gas project by Pacific Ag, d/b/a Sunnyside RNG LLC, and the City's Mitigated Determination of Non-Significance (MDNS), SEPA#2023-0200.

Center for Food Safety is a non-profit membership organization with offices in the Pacific Northwest, California, and D.C. CFS has members in the Lower Yakima Valley that are very concerned about the impacts of industrial dairy on their air and water, and the immediate impact of a methane digester of the size proposed, as well as its capacity to increase and further entrench the industrial lagoon and spray concentrated animal feeding operation (CAFO) model. **For the reasons below, the City should conduct a full Environmental Impact Statement (EIS) under the State Environmental Policy Act (SEPA), to evaluate the potentially significant impacts cause by this proposed operation.**

The MDNS is not adequate, particularly as it fails to take into account the full air quality impacts of this operation, and the indirect impacts it will have on the Valley by expanding the market for liquid cow manure and further entrenching and/or expanding the industrial CAFO dairy model that has caused water and air quality impacts to the communities in the Lower Yakima Valley for decades. The City cannot accept greenwashing by Pacific Ag in lieu of real environmental evaluation.

Legal Background

The Washington State Legislature, when it enacted the State Environmental Policy Act (SEPA), recognized that "each person has a fundamental and inalienable right to a healthful environment and that each person has a responsibility to contribute to the preservation and enhancement of the environment." RCW 43.21C.020(3). SEPA's substantive and procedural mandates overlay all regulatory and nonregulatory activities of Washington's governmental entities, including its municipalities. The City of Sunnyside, as the lead agency here, has the responsibility to "use all practicable means" so that the state and its people may:

> (a) Fulfill the responsibilities of each generation as trustee of the environment for succeeding generations;
>
> (b) Assure for all people of Washington safe, healthful, productive, and aesthetically and culturally pleasing surroundings;

> (c) Attain the widest range of beneficial uses of the environment without degradation, risk to health or safety, or other undesirable and unintended consequences;
>
> (d) Preserve important historic, cultural, and natural aspects of our national heritage;
>
> (e) Maintain, wherever possible, an environment which supports diversity and variety of individual choice;
>
> (f) Achieve a balance between population and resource use which will permit high standards of living and a wide sharing of life's amenities; and
>
> (g) Enhance the quality of renewable resources and approach the maximum attainable recycling of depletable resources

RCW 43.21C.020(2).

All branches of government, including municipalities, "shall: "Include in every recommendation or report on proposals for legislation and other major actions significantly affecting the quality of the environment, a detailed statement by the responsible official," including environmental impact, unavoidable adverse environmental effects, alternatives to the proposed action, local short-term uses of the environment versus the maintenance and enhancement of long-term productivity; and any irreversible and irretrievable commitments of resources. RCW 43.21C.030(2)(c).

The responsible official also "shall consult with and obtain the comments of any public agency which has jurisdiction by law or special expertise with respect to any environmental impact involved." *Id.* at 43.21C.030(2)(d); WAC 197-11-340(b) (shall send DNS to agencies with jurisdiction).

Major actions having a probable significant, adverse environmental impact require an EIS. RCW 43.21C.031. "Significant" in SEPA "means a reasonable likelihood of more than a moderate adverse impact on environmental quality." WAC 197-11-794(1). Significance involves "context and intensity" and thus does not lend itself to a quantifiable test. The rules state:

> The context may vary with the physical setting. Intensity depends on the magnitude and duration of an impact. The severity of an impact should be weighed along with the likelihood of its occurrence. *An impact may be significant if its chance of occurrence is not great, but the resulting environmental impact would be severe if it occurred.*

Id. at 197-11-794(2) (emphasis added). Even proposals intended to protect or improve the environment may require an EIS. SEPA regulations do not allow threshold determinations to be made by balancing the potential "good/bad" effects of a proposal. WAC 197–11–330(5).

The lead agency "shall make its threshold determination based upon information reasonably sufficient to evaluate the environmental impact of a proposal." WAC 197-11-335. If the SEPA Checklist does not include sufficient information, the responsible official may require the applicant to submit more information, make its own further study, consult with other agencies with

expertise, or decide that the action or its impacts are not sufficiently definite to allow analysis and commit to a timely, subsequent environmental analysis. *Id.* Only if the responsible official "determines there will be no probable significant adverse environmental impacts from a proposal" may they issue a determination of non-significance (DNS). WAC 197-11-340(1).

Impacts of Factory Farm Gas Digesters

Methane digesters that use CAFO waste are often referred to as creating "renewable natural gas" when they rely on the additional methane created by factory farms that use a liquid waste management system. Thus, the gas they produce is more appropriately termed "factory farm gas."

Industrial animal agriculture has already decimated small family farms and is built upon the exploitation of farm workers, communities, animals, and the environment. It is responsible for approximately 37% of all methane emissions in the United States.[1] Indeed, the only source of methane—an extremely powerful short term greenhouse gas—that is *increasing* is manure management. *Id.* Agricultural policy decisions that support the entrenchment and expansion of factory farms is a barrier to real mitigation of the climate crisis and to more sustainable and just farming methods and a diversified food system.[2]

Factory farm gas production is only compatible with industrial animal agriculture that produces far more waste than can be responsibly managed (as we have seen in the Lower Yakima Valley for decades), and perversely encourages the use of liquified manure management systems —the cheapest and most environmentally destructive form of manure management. Factory farm gas incentives have already created a "manure gold rush" by establishing revenue streams for the manufacture of liquid manure.[3] These digester facilities only incentivize the further expansion and consolidation of the largest factory farms, which are already major sources of air and water pollution in the Lower Yakima Valley, and sources of environmental injustice.

Increased herd sizes will significantly increase the amount of methane released into the environment through enteric emissions, while also continuing to increase emissions of other GHGs such as nitrous oxide and carbon dioxide. Indeed, research is finding that GHG emissions from factory farm gas production and use is significantly higher than previously understood, undercutting the supposed climate benefits of factory farm gas even more.[4]

[4] *See, e.g.*, Semra Bakkaloglu et al., *Methane Emissions Along Biomethane and Biogas Supply Chains Are Underestimated*, 5 One Earth 724–736 (June 17, 2022),

Not only are there air quality concerns in the immediate vicinity of these operations, but they result in the burning of methane that further contributes to climate change and continues and expands the use of fossil fuel infrastructure. The City must take into account both the impacts of a changing climate on the proposed facility and how the facility will contribute to further greenhouse gas emissions.

Digesters do nothing to improve the groundwater conditions under existing CAFOs, where seepage to groundwater comes not just from lagoons holding liquid manure wastewater, but also from pens, manure and feed storage areas, and land application fields. Residents in the Lower Yakima Valley already suffer from drinking water contaminated with high levels of nitrates.[5]

Digesters themselves create additional pollution and public health risks. First, they rely on dirty fossil natural gas infrastructure, including leaky pipelines, which leads to the further entrenchment of this infrastructure. Second, they leak methane and manure and can even explode. For example, a digester on a North Carolina factory farm recently ruptured, spilling three million gallons of "gelatinous gray foam"— enough "to fill more than four Olympic-sized swimming pools."[6] At least 37,000 gallons of the waste reached wetlands. *Id.*

An EIS is Required Under SEPA

The MDNS and the reports it relies on, including the SEPA checklist, do not consider the full impacts of this facility, including its direct impacts of increasing air pollution in the immediate area, the increase to greenhouse gas emissions overall, and the potential for spills or explosions, and its indirect impacts of incentivizing the expansion and entrenchment of CAFOs in the Lower Yakima Valley. The City must consider all direct, indirect, and cumulative adverse impacts before making a DNS. As to air pollution, the City is only now releasing the New Source Review authored in February. The Yakima County Clean Air Agency is the agency responsible for air quality permitting, and it has not even commented on this proposal, in violation of RCW 43.21C.030(2)(d)

[6] Adam Wagner, *'Really terrible science experiment' leads to weeks-long spill from NC hog-waste lagoon*, The News & Observer (Sep. 6, 2022), *see also*, Sound Rivers, *Wayne Co. toxic spill exposes lack of NCDEQ transparency* (Sep. 7, 2022), https://soundrivers.org/wayne-co-toxic-spill-exposes-lack-of-ncdeq-transparency/ (the spill was likely closer to 3 million gallons of nutrient- and bacteria-laden foam; 37,400 gallons was the number initially cited by the facility in its public notice, but months later they stated that the actual number was approximately 3 million gallons).

and WAC 197-11-340(b). Further, it is commenters' understanding that the Clean Air Agency rejected the February New Source Review application and that no further changes have been made. Nor have permits been granted for stormwater and other water quality issues, meaning that such analysis has yet to be completed. The SEPA Checklist says nothing about what will happen to digestate after the methane is extracted, and how water quality will be protected from its spreading. Without sufficient information about the air and water quality impacts of this facility, the City cannot legally make a DNS.

Even if impacts like explosions are not highly likely, the City must still take them into account. RCW 197-11-794(2) ("An impact may be significant if its chance of occurrence is not great, but the resulting environmental impact would be severe if it occurred."). Emissions of methane and hydrogen sulfide are expected, and these gases are hazardous, and hydrogen sulfide is toxic. Further, the SEPA Checklist does not explain what CAFOs will be paid for their waste, going directly to the question of whether this operation will contribute to the entrenchment and increase in size of CAFOs in the Lower Yakima Valley.

Significance depends on context and intensity, and here there is enough information to point to a reasonable likelihood of more than a moderate adverse impact on environmental quality, but also a lack of information to say there will be no probable significant adverse environmental impacts. WAC 197-11-335.

Environmental Justice

These FFG digesters directly implicate environmental justice, and this proposed digester will be sited in a rural, low-income, community of color. Sunnyside's population is 86.2% Hispanic. And yet the City failed to do any significant outreach to this community, including in Spanish. BIPOC populations across the country are more likely to live next to factory farms and thus bear the burden of pollution from these facilities. The same is now true of factory farm gas digesters.[7]

The City is not operating in a vacuum, but rather in a state with extensive resources to more effectively engage with environmental justice populations, including the Washington State Environmental Justice Task Force and its recent Report and the state's Health Disparities Mapping Tool. Given the resources it is unacceptable that the City failed to conduct sufficient outreach to community members and neighbors of the proposed operation on the SEPA MDNS. No one from the City even appeared at a community organized public meeting held on November 30. The City further noted an appeal deadline, scheduled an appeal hearing, and then canceled it. Appeals to the local legislative body must be held under RCW 43.21C.060 where a nonelected official conditions a proposal under SEPA, as occurred here. Sunnyside Code, Ord. 1475 § 2, 1984, (adopting appeals process established in WAC § 197-11-680).

[7] Southern Envtl. Law Center, Complaint under Title VI of the Civil Rights Act of 1964, 42 U.S.C. § 2000d, regarding the North Carolina Department of Environmental Quality's Issuance of Permit Nos. AWI310035, AWI301139, AWI230466, and AWS820005 (Sep. 27, 2021), https://www.southernenvironment.org/wp-content/uploads/2021/09/2021-09-27-Title-VI-Complaint-Index-DEQ-Biogas-Permits.pdf.

Finally, this operation was awarded a $500,000 grant from the WA Dept. of Commerce, without any environmental justice analysis under the HEAL Act.[8]

Solid-liquid separation

ABSTRACT

Manure management at dairy production facilities, including anaerobic digestion (AD) and solid-liquid separation (SLS), has shown strong potential for the abatement of greenhouse gas (GHG) and ammonia (NH_3) emissions. However, previous study results are inconsistent and the combined effect of AD + SLS remains to be quantified. This study evaluated the effects of AD, SLS, and AD + SLS on GHG and NH_3 emissions during manure storage through land application over nine months. AD and SLS alone significantly ($P < 0.05$) reduced total GHG emissions for storage and land application compared to untreated manure slurries by 25% and 31%, respectively. The majority of that reduction was from methane during storage. SLS had a greater potential for methane reduction in storage than AD, but the variability in digester performance likely impacts the reduction potential. Digestion with subsequent separation further decreased CH_4 emissions from 3.9 g CO_2-eq to 1.3 g CO_2-eq, but increased emissions of nitrous oxide (N_2O) from 0.6 g CO_2-eq to 2.0 g CO_2-eq during storage eliminating a further reduction of GHG emissions as compared to AD alone. AD resulted in a gas emission tradeoff as it increased NH_3 emissions by 81% during storage, which could be mitigated by subsequent SLS, manure storage covers, or other beneficial management practices.

1. Introduction

In 2013, 7.7% of all U.S. greenhouse gas (GHG) emissions were from agricultural sources. Gaseous losses from ruminant livestock in the form of manure management were responsible for 15.2% of agricultural emissions (USEPA, 2015). In addition, GHG emissions from dairy manure management increased by 53% from 1990 to 2012 and are expected to continue to rise; therefore, it is critical to recommend efficient manure management mitigation strategies to dairy producers to abate overall agricultural GHG emissions (USEPA, 2015). Many different strategies have demonstrated potential to reduce methane (CH_4), nitrous oxide (N_2O), and ammonia (NH_3) emissions from manure (Montes et al., 2013; Ndegwa et al., 2008). For example, manure processing using anaerobic digestion (AD) can reduce CH_4 emissions and solid-liquid separation (SLS) can reduce both CH_4 and N_2O emissions (Amon et al., 2006; Chadwick et al., 2011; Clemens et al., 2006; Meyer-Aurich et al., 2012).

AD is a microbial process that degrades organic material, such as cattle manure, in the absence of oxygen, producing biogas, which is primarily composed of CH_4 and carbon dioxide (CO_2). Biogas can be captured and combusted to generate electricity, directly burned for heating applications, or further upgraded for use in higher value applications such as vehicle fuel. These processes reduce the net emissions impact from feedstocks natural decomposition as CH_4 in biogas is converted to CO_2 during combustion. When CH_4 is captured and used as an energy source it can also reduce the life cycle depletion of fossil fuels from manure management at a dairy facility by 43% as grid-based electricity is replaced by biogas-based electricity (Aguirre-Villegas et al., 2014). The effluent leaving the digester, known as digestate, has modified chemical content (e.g. total solids, carbon, ammonium (NH_4), and pH), contains more soluble plant nutrients due to mineralization, and has less degradable biomass than the original substrate resulting in changes in GHG and NH_3 emissions (Clemens et al., 2006). These changes can result in an additional benefit as the effluent from the digester has reduced organic matter, which has

shown potential to mitigate GHG emissions during storage and after land application (Amon et al., 2006; Clemens et al., 2006; Hafner et al., 2013). Amon et al. (2006) found that digestion reduced total GHG emissions by 60% from the untreated slurry due to the reduction of CH_4 emissions, however the results from this study should be used with caution as there was no replication.

While there exists a potential for GHG emissions reductions, a tradeoff may exist in using digestion to mitigate manure GHG emissions, as some of the changes in the manure composition can promote NH_3 emissions following digestion. During the AD process, methanogens and other microorganisms break down proteins, amino acids, and urea forming NH_4 (Bernet et al., 2000). In addition, mineralization of organic N and volatile fatty acids during AD increases manure pH and available N (Petersen and Sommer, 2011), factors which increase NH_3 emissions. Despite these known mechanisms, studies measuring NH_3 emissions after AD have been inconsistent. Amon et al. (2006) found that NH_3 emissions from digested manure storages were similar to untreated. After application, this same study found that NH_3 emissions for the digested manure were 15% greater than the untreated manure. On the contrary, Neerackal et al. (2015) reported significantly higher NH_3 emissions from manure storage after AD, but a reduction of NH_3 emissions after manure land application. In addition, the variability in results highlights the importance of conducting additional research that explores the effect of AD on NH_3 emissions.

Solid-liquid separation is a process in which manure solids are mechanically separated from manure liquids to reduce storage capacity and increase flexibility of manure management (Christensen et al., 2013). The liquid portion after separation has a lower amount of organic matter and carbon available for methanogenesis resulting in lower CH_4 production potential. In comparison with liquid manure, storage of separated manure solids results in an environment that is predominately aerobic, eliminating the anaerobic conditions necessary for CH_4 production and thus decreasing CH_4 emissions. Fangueiro et al. (2008) found that separate storage of the liquid and solid fraction resulted in a reduction of CH_4 emissions of approximately 35% when compared to the raw manure. Further reductions during storage may be possible if AD is utilized before separation as it can lower carbon in the manure prior to separation, but exploring the effect of combining AD and SLS on GHG and NH_3 emissions has been largely absent from the literature.

Similar to AD, a tradeoff may exist in reduction of gaseous emissions from SLS as it can increase NH_3 and N_2O emissions in the separated solids. Aerobic solid manure storage systems promote the production of NH_4 and without a subsequent anaerobic environment for nitrification some NH_4 is volatilized as NH_3 (Hansen et al., 2006). As with AD, the results have been inconsistent regarding the effects of SLS on emissions. Amon et al. (2006) found that SLS increased total NH_3 and N_2O emissions from storage and application by 77% and 19% respectively, with a majority of emissions from the composting of the solid portion. Conversely, Hou et al. (2015) observed no significant difference in N_2O emissions between separated liquids from unprocessed manure and reported that the separated solids show lower N_2O emissions than unprocessed manure in terms of percentage of N applied. Neerackal et al. (2015) also found no significant difference of NH_3 emissions between raw manure and separated liquids.

Altering the composition of manure though AD and SLS can affect GHG and NH_3 emissions from downstream processes, which highlights the importance of keeping track of the emissions throughout all manure handling steps. Studies have focused on specific processing technologies (e.g. only storage or only land application) or specific emissions (Dinuccio et al., 2011; Koirala et al., 2013; Neerackal et al., 2015) but there is limited literature quantifying both GHG emissions and NH_3 emissions from both manure storage and land application and from the same manure stream. Amon et al. (2006) conducted a more comprehensive assessment of emissions from stored and applied manure, but the study contained no replication and followed emission for only 20 days after application. While the prior work conducted in this area was critical to develop data trends, continued work is needed to provide more comprehensive evaluation of manure processing systems, particularly the combination of processing systems. This study is one of the first to compare the magnitude and direction of GHG and NH_3 emissions from manure storage and land-application after combined AD and SLS from the same manure stream.

Literature on CO_2 emissions from processed manure using AD and SLS is also limited. Researchers generally do not quantify gaseous losses of CO_2 from manure as they have been previously absorbed and metabolized by plants that constitute the dairy ration, thus, being part of the carbon cycle and not an additional source of CO_2 (Kulling et al., 2001). While this logic is sound, it is still important to quantify CO_2 emissions to understand the carbon cycling at a dairy farm. In this study, we investigated the influence of AD, SLS, and the combination of AD and SLS on CO_2, CH_4, N_2O, and NH_3 emissions during storage and for one growing season after manure application to the field.

2. Methods & materials

Emissions from processed and unprocessed manure during storage and land application were monitored for CH_4, CO_2, N_2O, and NH_3. Manure collected was measured over a 182-day storage study and upon completion was applied to the field where gas measurements continued for 126 days.

2.1. Manure collection and storage

Manure streams were collected in the pump room of two dairy facilities in 0.21 m^3 barrels for the storage portion of the study. Raw manure at farm 1 (R1), digested manure at farm 1 (D1), digested separated liquids at farm 1 (DL1), and digested separated solids at farm 1 (DS1) were collected from a dairy with a mixed plug-flow digester and screw press separators. The digester operates at a mesophilic range and is loaded with skid steer collecting manure three times per day. Two Bauer™ model # 855 screw press separators are used at the facility for manure solid-liquid separation after digestion with a 260 mm press and 520 mm dewatering section with 0.5 mm screen widths. After separation, at this facility, the digested solids are used for bedding and the separated liquids are stored and then land applied. Raw manure at farm 2 (R2), separated liquid at farm 2 (L2), and separated solids at farm 2 (S2) were collected from the USDA dairy facility located in Prairie du Sac, WI. The dairy uses wheat straw for bedding and collects manure with an automatic scraper. Manure is then pumped to a Vincent™ KP-10 screw press separator with a 372 mm press section and 800 mm dewatering section with 0.381 mm screen widths. Manure was collected from two farms as sampling digestion and separation alone and the combination of the two was not possible at the farm scale. At farm 1 only digested manure (D1) was an input to the separator and no infrastructure existed to separate only R1, therefore an additional farm was required to analyze the effects of separation alone.

Manure slurries and separated liquids were stored in 0.21 m^3 plastic barrels filled with 0.185 m^3 of each manure stream from November 2013 to May 2014. In Wisconsin, separated solid piles are often stored in large unturned piles, impending oxygen supply. Therefore, separated solids in the study were stored in barrels with the lid open. A headspace of 15–20 cm was left at the top of the barrel for gas emission measurements. The mass of manure was

measured at the beginning and end of the storage period (Table A.1 found in the Appendix) and the exact headspace was measured weekly to calculate gas fluxes. Manure streams were collected in triplicate and one barrel was left unfilled to measure ambient air gas concentration as a control.

The manure barrels were stored in an open barn which ranged in temperature from 1 to 18 °C during the study period and were open to the environment when emissions measurements were not being collected to simulate actual manure storage conditions (including digestate which is stored in uncovered anaerobic storages). Concentrations of CH_4, CO_2, N_2O, and NH_3 were measured from the headspace of the barrel once a week by placing a lid over each barrel and using the a Gasmet™ Fourier Transform Infrared Spectroscopy (FTIR) gas monitor (Model DX4030, Gasmet Technologie Oy, Helsinki, Finland) that detected gaseous compounds by absorbance of infrared radiation at 10 s intervals (Powell and Vadas, 2016). The lid connecting the FTIR to the barrel was designed with an inlet, outlet, and an 18 mm diameter opening to vent to the atmosphere and equilibrate pressure from within the barrel to the barn. The chamber headspace air was pulled into the FTIR for CH_4, CO_2, N_2O, and NH_3 concentration measurement through the inlet of the chamber, and the air was returned back into the chamber's headspace through the outlet, resulting in closed loop air circulation required for measuring cumulative gas concentrations (Neerackal et al., 2015; Sun et al., 2014a). At the time of sampling, gas was cycled through the FTIR at a rate of 2 L per minute for 7 min and concentrations were measured every 20 s. Immediately before each barrel was sampled, headspace depth and manure temperature were recorded and the FTIR was calibrated with N_2 gas.

A closed loop chamber measurement system was used for its ability to measure low gas concentrations and provide air mass transport required for NH_3 emission measurement. Manure storages with liquid or slurry manure are mainly anaerobic, and without an organic crust at the surface N_2O production is low (Sommer et al., 2000). After manure is applied to the field, most of the CH_4 is released within the first few days from a pool of dissolved CH_4 trapped in the manure (Chadwick and Pain, 1997; Chadwick et al., 2000; Clemens et al., 2006; Sommer et al., 1996). Dynamic chambers with an open air flow system prevent accumulation, reducing concentrations and ultimately decreasing the sampling resolution of CH_4 and N_2O emissions from the study. Additionally, closed loop measurement systems have the advantage over static chambers as their design facilitates air transport as required for NH_3 flux measurement. While static chambers may underestimate NH_3 emissions (Miola et al., 2015), Neerackal et al. (2015) found that closed loop chambers resulted in similar emissions to laboratory evaluations using flux chambers.

Manure samples were collected at the start of the experiment and monthly throughout the storage study. A Sludge Judge® sampler (Nasco, Fort Atkinson, WI, U.S.A.) was used to collect a composite sample along the entire depth of the barrel. Chemical analysis included measurements for pH, electric conductivity (EC), $NH_4 + NH_3$, total solids (TS), volatile solids (VS), and total kjeldahl nitrogen (TKN), total carbon (total C), acid detergent fiber (ADF), neutral detergent fiber (NDF), and hemi-cellulose (Table A.2). Samples were refrigerated and analyzed for pH and TS analysis within one week, the remaining analysis was completed in 28 days on samples that were diluted and preserved.

Manure characteristics from each manure treatment varied in chemical composition at the beginning of the study. Both D1 and DL1 had greater concentrations of $NH_4 + NH_3$ compared to R1 (Table 1). Digested manures also had lower solids content, VS, aNDF, hemi-cellulose, and C/N ratio. Separation decreased the solids and carbon content of the liquid portion at both farms from their raw slurries. The separated solids had higher concentrations of all parameters except EC. Subsequent separation following digestion further decreased the VS, ADF, aNDF, and hemicellulose.

Table 1
Initial manure characteristics for all treatments. Farm 1 raw manure (R1), farm 1 digested manure (D1), farm 1 digested separated liquid (DL1), farm 1 digested separated solids (DS1), farm 2 manure (R2), farm 2 separated liquid (L2); farm 2 separated solids (S2).

Characteristics	R1	D1	DL1	DS1	R2	L2	S2

2.2. Manure field application

After 182 days of storage, manure was applied in bands to 1.5 m by 2.1 m plots with bare soil and immediately incorporated to a depth of 17 cm at the USDA Dairy Forage Research Station in Prairie du Sac, WI in May 2014. Manure was applied to plots at an application rate of 320 kg N ha^{-1}, Table 1. Application rates were determined using the TKN content of the manure sampled on day 124 of the storage experiment, 58 days before the application of manure. Emissions of N_2O and NH_3 in the days prior to the application were measured and used to estimate N lost from each manure treatment from day 124 to the day of application which was less than 5%. The percentage of ammoniacal-N was different between treatments and the liquid slurries had more available N applied (Table A.1). Typical N application rates in Wisconsin range from 140 to 235 kg available N ha^{-1} for loamy soils with a high yield potential (Laboski and Peters, 2012). A supplemental application of urea at a rate of 82.6 kg N ha^{-1} was applied 44 days after manure application to simulate actual field conditions, as a supplemental N application is often necessary for corn as indicated by the recommended N application rates. The urea was pretreated with a nitrogen stabilizer with a urease inhibitor, Agrotain© Ultra, at a rate of 3.1 L per metric ton of urea. A control plot that did not receive any manure was established to capture soil gas fluxes.

Treatments were applied to the field using a randomized complete block design. Each barrel was applied to two plots and therefore the number of replicates from the storage to field study went from three to six. The digested solids, DS1, were not applied to the field as digested solids are commonly used for bedding or other purposes and not land applied. Four rows of field corn were planted in each plot at 76.2 cm apart making up two border rows and four rows for harvest analysis. A rectangular 0.3 m^2 anchor was placed near the center of each plot and a chamber lid was placed on the anchor once a week to calculate CH_4, CO_2, N_2O, and NH_3 flux using the Gasmet™ FTIR gas analyzer described above. The chamber lid consisted of a 0.03 m^3 rectangular lid with three 6.35 mm cylindrical tube ports one for the inlet, one for the outlet, and one exposed to the atmosphere for pressure equilibration. Emissions of CH_4, CO_2, N_2O, and NH_3 from field plots were measured following a similar protocol to that of field manure storage studies. Soil temperature and moisture were measured during each gas flux measurement. Soil samples were taken every other week during the trial at a 0–10 cm and 10–20 cm depth for analysis of $NO_2 + NO_3$ and $NH_4 + NH_3$.

2.3. Data analysis

Cumulative emissions, expressed in terms of carbon dioxide equivalents (CO_2–eq), were calculated using piecewise interpolation between sampling points and were determined for a 100 year horizon with characterization factors of 25 for CH_4 and 298 for N_2O (CML, 2001). Biotic CO_2 emissions from manure were not incorporated in the total GHG emission accounting, but are included in the study for carbon balance purposes. Indirect N_2O emisisons from NH_3 volatilization were not included in the analysis.

To compare processed solid and liquid manures after AD and SLS, emissions were calculated per mass of raw unprocessed manure for each scenario. The separation efficiency was calculated based on TS for all separated manures to conduct an equivalent comparison between scenarios. Based on these efficiencies, 97% of the raw manure from farm 1 goes to the liquid fraction (DL1) and 3% goes to the solid fraction (to DS1), and 99% of the raw manure from farm 2 goes to the liquid fraction (L2) and 1% to the solid fraction (S2). Finally, gas emissions from the separated solids and liquids were multiplied by mass fraction corresponding to the raw manure and totaled for comparison. Combined liquids and solids at farm 1 are designated DL1 + DS1 and L2 + S2 at farm 2.

A one tailed *t*-test assuming equal variance was conducted to compare intial charateritics of raw manure and processed manure at the same farm. Statistical analysis was performed using the SAS software version 9.4 (SAS Institute Inc., Cary, North Carolina). A one-way ANOVA (Proc ANOVA) was calculated to determine statistical differences between manure characteristics and gaseous emissions separately for manures from farm 1 and farm 2. A Tukey's studentized range test (HSD) was conducted to compare differences between treatments at alpha = 0.05 confidence level. Farm 1 and farm 2 were not grouped for statistical analysis due to dissimilar chemistry in manure at each farm. It was determined that there was no significant block effect on field emissions, therefore the emissions from the entire study for each treatment were determined by adding the emissions from the storage study to the average emissions of the two field plots for each respective treatment.

Emissions, manure characteristics, and soil characteristics were used in model selection to determine predictors of gaseous emissions. To determine correlation between gaseous emissions and manure and soil characteristics a Pearson Correlation Coefficient test of independence (Proc CORR) was ran in SAS. A multiple linear regression (Proc REG) using the stepwise selection function (Proc GLMSELECT) was calculated to predict gas emissions from CO_2, CH_4, N_2O, and NH_3 determined from manure and soil characteristics. However only the NH_3 regression with parameters of EC, temperature, pH, and total N% of manure during storage is reported as it was the only gas for which a model was statistically significant.

3. Results and discussion

3.1. Manure characteristics

During storage, the TS content of the liquid and slurry manures remained relatively consistent while the TS content of the solid manures increased approximately 40% for both DS1 and S2 over the storage period due to moisture loss (Fig. B.1). The increased porosity and temperature of the solid manures likely caused them to dry at a much faster rate than the liquid and slurry manures. The VS from all manures remained relatively unchanged during the first 30 days except for DL1 and DS1 (Fig. B.1). After the first 30 days, VS content remained relatively constant for all manures. Total C and TKN showed very small differences between sampling dates and no discernible trend could be seen as the sampling and analytical variation may have caused values to increase then decrease (Fig. B.1). The raw slurry from farm 2, R2, had substantial crust formation within the barrel and maintained an approximately 75% crust cover (visual estimate) during storage due to the use of straw bedding. The raw slurry from farm 1, R1, displayed some crusting with crust coverage less than 25% of the surface area given that digested separated solids were used for bedding at this farm.

3.2. Ammonia

Digestion, D1, resulted in an 81% increase in cumulative NH_3 emissions compared to R1 over the entire study period (Fig. 1A) similar to previous studies (Koirala et al., 2013; Neerackal et al., 2015; Sun et al., 2014b). This increase in cumulative NH_3 emissions is expected due to the mineralization of organic N through the digestion process which increased $NH_4 + NH_3$ concentrations in manure from R1 to D1 by 22%. In the case of NH_3, separation following digestion, DL1, was able to significantly reduce this impact by 28% as compared to D1, although overall emissions were still 32% greater than R1. Removal of TS through separation following digestion had a significant effect on reducing NH_3 emissions of DL1 from D1, similar to Neerackal et al. (2015), but the specific mechanism for reduction is not known as the $NH_3 + NH_4$ concentration did not decrease from D1 to DL1. Further, separation alone, L2 + S2, did not significantly reduce NH_3 compared to R2. This is thought to be due to the presence of a crust on R2 which

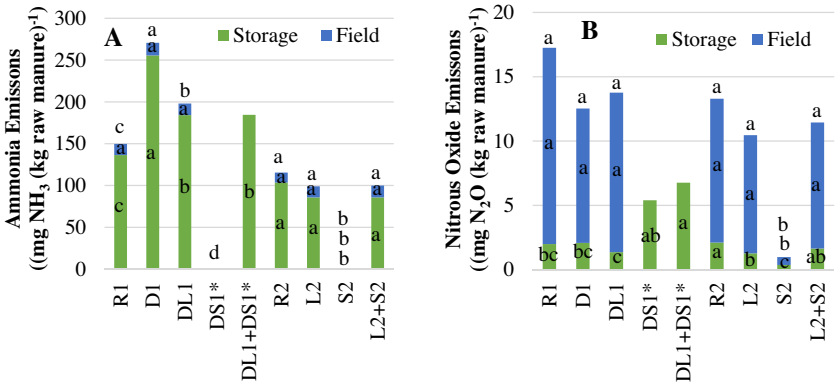

Fig. 1. Nitrogen emissions from liquid slurries and processed manures at both farms: (A) Ammonia (NH_3) and (B) Nitrous Oxide (N_2O). Treatments with similar letters (a, b, and c) at each farm did not show statistical significant difference at the α=0.05 level, ANOVA was ran separately for each farm. *DS1 was removed for the field portion of the study, and was not applied to experimental plots.

served as a barrier to emissions (Aguerre et al., 2012). L2 did not have a crust form on the storage and had elevated NH_3 emissions. While digestion increased NH_3 emissions, it is important to note that there are many management practices, such as manure storage covers and using injection for land application, that can overcome this issues to reduce the overall impact.

Liquid and slurry manures resulted in significantly greater NH_3 emissions than separated solids during storage (Fig. 1A), suggesting mitigations strategies should be targeted at liquid and slurry manures. While some studies suggest this is the case (Dinuccio et al., 2011, 2008) there are some that measured increased NH_3 emissions from manure solids (Amon et al., 2006). An increase in NH_3 emissions is likely when the method of solid manure storage increases aeration (Hansen et al., 2006). Amon et al. (2006) found that when separated solids are aerated NH_3 emissions will increase, up to 77% greater than anaerobically stacked manure solids.

Field application resulted in no treatment differences for NH_3 emissions, likely due to both the measurement system used and the manure incorporation method which has been shown to mitigate NH_3 emissions (Meisinger and Jokela, 2000; Powell et al., 2011). There is abundant literature on reductions of NH_3 when manure is rapidly incorporated (40–90%) (Dell et al., 2011; Hristov et al., 2011; Ndegwa et al., 2008; Powell et al., 2011; Webb et al., 2004; Wulf et al., 2002). However, while incorporation likely reduced the NH_3 concentrations of all treatments, the closed loop measurement system may have underestimated cumulative emissions. Miola et al. (2015) found that cumulative NH_3 emissions were underestimated by 23% when using static chamber 22 days after manure application. This difference was not statistically significant for 75% of the trials, and the difference decreased with the addition of a fan which was more similar to our closed loop system. In addition, Neerackal et al. (2015) determined that NH_3 emissions measured with a closed loop system (very similar to the design in this study) underestimated cumulative emissions compared to a laboratory dynamic system by 32–66%, but found the treatment differences remained consistent between the two measurement systems. While closed loop systems have been used extensively in literature, the results may underestimate NH_3 emissions overall, particularly when ammoniacal-N is low and the measurement period is short.

A multiple linear regression model was developed to predict NH_3 emissions from storage based on EC, manure temperature, pH, and total N. A significant regression was found ($F(4, 55) = 26.51$, $p < 0.0001$), with an R^2 of 0.659. Measured parameters predicted NH_3 emission ng (kg-manure s)$^{-1}$ according to Formula (1) where α = electric conductivity (us/cm), β = manure temperature (°C), γ = pH, and δ = Total N (%).

$$y = 0.006 + 0.447\alpha + 3.49\beta + 23.5\gamma + 0.006\delta \quad (1)$$

Manure pH and temperature had significant positive regression weights indicating, as expected, that manure storages with higher pH and temperature resulted in higher emissions of NH_3. Total N and EC reduced the error of the regression model, improving fit as indicated by the R^2 value, although their inclusion into the model was not statistically significant.

3.3. Nitrous oxide

Nitrous oxide emissions were greater for solid manures during storage compared to liquids and slurry manures, but the largest emissions of N_2O for all treatments were following land application of manure (Fig. 1B). N_2O from slurry and liquid storage is not expected to be a significant source of the total N_2O from manure systems as the anaerobic conditions prevent production, which is supported by literature (Monteny et al., 2001; Sommer et al., 2000). The N_2O from digested separated solids was much higher than the separated solids without digestion, where DS1 had emissions of 5.4 mg N_2O/kg manure and S2 has emissions of 0.4 mg N_2O/kg manure. Although both manures were similar in composition, including similar TKN concentrations of 1.35% and 1.24%, respectively, the mineralization during digestion resulted in an increase in $NH_4 + NH_3$ concentrations of 327 mg N/L for DS1 while S2 was much lower at 71 mg N/L. Higher concentrations of NH_4 have been linked to increased N_2O production (Sommer et al., 2000). While the increase in $NH_4 + NH_3$ through digestion likely contributed to the increase in N_2O, differences in animal diets and separator designs could also impact components contributing to N_2O emissions in the solid streams. While DL1 had a reduction in N_2O emissions as compared to R1, this mitigation was negated by DS1 as DL1 + DS1 significantly increased emissions from R1 by 240% in storage.

Separation has a 40% reduction in N_2O emissions from L2 as compared to R2 during storage, likely due to the crust formation in R2. Natural crust formation has been shown to enhance N_2O emissions (Aguerre et al., 2012) as it provides aerobic and anaerobic environments necessary for N_2O production (Sommer et al., 2000). The lack of a crust in the raw slurry at farm 1, R1, may also explain why there was no treatment difference in N_2O emissions following separation at farm 1. While separation can achieve a reduction in N_2O emissions from R2 to L2 during storage, the N_2O emission from S2 were much higher, resulting in a net increase from storage. While there was a 22% increase in the $NH_4 + NH_3$ concentration from R1 to D1, there was no corresponding increase in N_2O concentrations suggesting crust cover may be a more important factor for the production of N_2O emissions from manure storage. This theory is supported by those who suggest localized sites are critical for N_2O production (Rotz et al., 2012). Again, separation following digestion increased overall N_2O emissions from storage due to elevated N_2O emissions from the digested solids. However, in some cases solids are strictly land applied reducing the amount emitted from storage.

During the field portion of the study, the digested liquid manures, D1 and DL1, had N_2O emission reductions of 31% and 18% from R1, respectively (Fig. 1B). These reductions were not statistically different, which is explained by the relatively large standard deviation in emission of 4.3 mg N_2O kg raw manure^{-1} of R1. During the first 80 days following application, with an exception of emissions on the first day and day 34, N_2O losses remained relatively constant. During this period soil $NO_2 + NO_3$ remained between 2 and 4 ppm and $NH_3 + NH_4$ decreased somewhat linearly from 6 to 8 ppm to around 2 ppm (Fig. 2). Soil moisture rose to ~50% on day 35 corresponding to a peak in N_2O emissions. An increase in soil moisture would have resulted in less oxygen which would have affected rates of denitrification (Bergstermann et al., 2011) thereby increasing N_2O emissions. The addition of urea 44 days after application resulted in an increase in soil $NH_3 + NH_4$ on day 77 (Fig. 2). The delay in release of $NH_3 + NH_4$ was most likely due to the use of the urease inhibitor. The increase in soil $NH_4 + NH_3$ on day 77 resulted in a peak in N_2O emissions on day 84. Soil temperature had no observed effect on N_2O emissions during this study (Fig. 3), similar to findings by Sommer et al. (2000).

The indirect formation of N_2O from NH_3 could increase GHG emissions from D1 by an additional 1.19 mg N_2O kg raw manure^{-1} if the 0.01 kg N_2O-N kg NH_3^{-1} IPCC factor for N_2O emissions from NH_3 is considered (Eggleston et al., 2006). This would increase the overall total GHG emission of D1 by 2% or from 7.43 to 7.55 g CO_2-eq kg raw manure^{-1}, which is still lower than the GHG emissions from R1 of 9.93 CO_2-eq kg raw manure^{-1}.

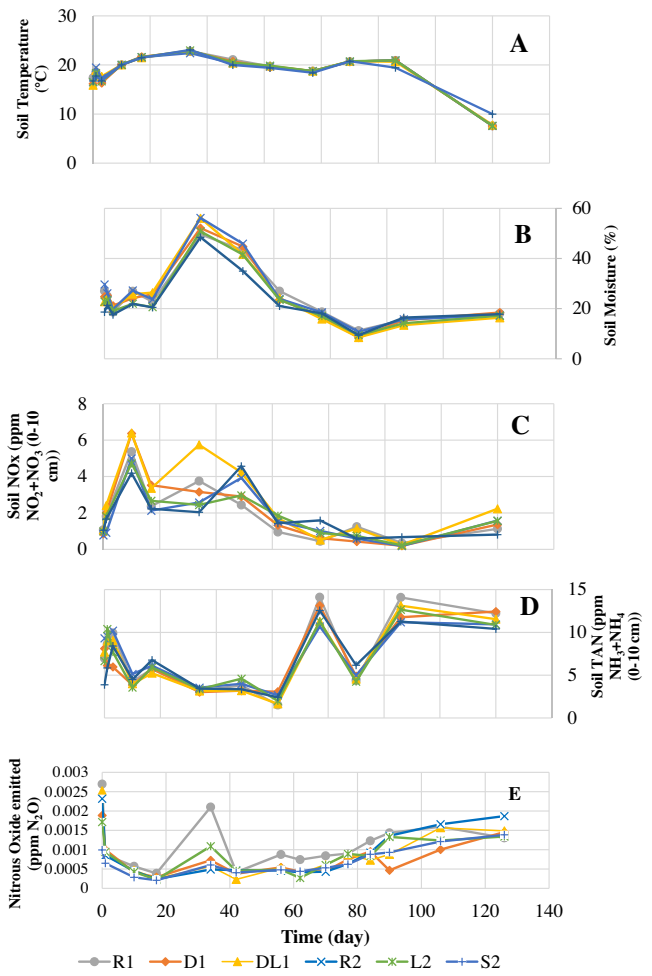

Fig. 2. N_2O emissions and soil characteristics over time (days) for each treatment over the field portion of the study: (A) Soil Temperature, (B) Soil moisture, (C) Soil $NO_2 + NO_3$ at the 0–10 cm depth, (D) Soil $NH_3 + NH_4$ at the 0–10 cm depth, and (E) N_2O emissions.

3.4. Methane

Methane emissions were greater during storage than land application for all treatments, as expected (Fig. 3A). AD and SLS both showed potential for mitigating CH_4 emissions during storage. The digested liquid manures, D1 and DL1, had a 25% and 68% reduction in CH_4 emissions, respectively, during storage compared to R1, which can be explained by the significantly lower initial VS, NDF, TS, and C content (Table 1) than R1 (7% at $p < 0.05$ for D1 and 19% at $p < 0.001$ for DL1). Volatile solids and C are reduced during digestion as methanogens break down biomass to create CH_4 and CO_2 which is then captured and combusted. The separated solids from both farms, DS1 and S2, produced negligible amounts of CH_4. Solid manure storage lacks the anaerobic conditions necessary for methanogenesis, as oxygen is allowed to penetrate due to its porosity, reducing the amount of CH_4 produced as compared to liquid or slurry manures. Additionally, easily degradable carbon for methanogenesis could remain in the liquid portion reducing the methane production potential of the separated solids.

Methane emissions were reduced during storage from D1 (25%), DL1 + DS1 (68%), and L2 + S2 (46%) than their respective raw slurries, R1 and R2, indicating that separation had a greater reduction in methane during storage than digestion. The reduction due to digestion in likely highly variable based on digester performance. The CH_4 emissions reductions during storage from DL1 + DS1 were significantly less than D1 as stated above, indicating that separation further reduces CH_4 following digestion at a similar percentage to separation alone. Separated liquid manure from farm 2, L2, showed no significant difference when compared to R2 even though there was a very large change in CH_4 emissions due to a large standard deviation, 110 mg CH_4 kg raw manure^{-1}. Emissions of CH_4 per gram of VS and CH_4 per gram of C were inconsistent among treatments, indicating that other physical and chemical differences, such as NDF, TS, environmental conditions, and crust coverage may have also played a role in CH_4 emissions.

3.5. Cumulative greenhouse gas emissions (nitrous oxide and methane)

All manure treatments released a majority of the total GHG emissions within the first 30 days of storage (Fig. 4). Emissions decreased over the next 49 days as temperatures in the barn dropped below 10 °C. When the temperatures increased above 10 °C around day 120 for the remainder of the study there was a corresponding increase in emissions. As expected, A Pearson Correlation Coefficient test of independence showed a strong interaction ($r = 0.684$, $p < 0.0001$) between GHG emissions and manure temperature. After land application of manure, cumulative GHG emissions for all treatments increased relatively linearly until

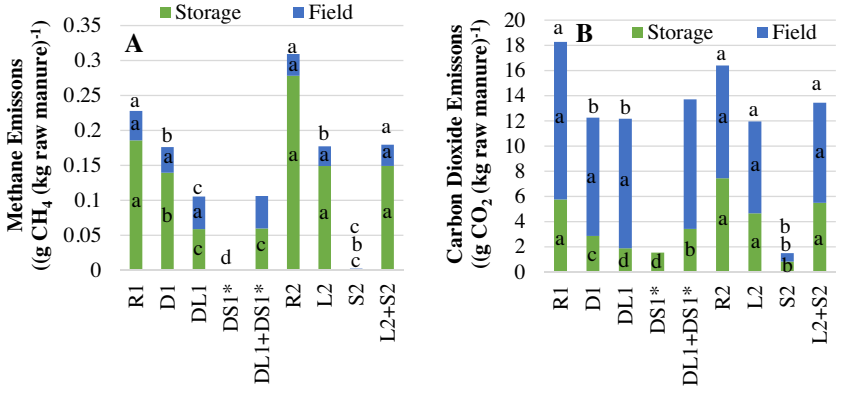

Fig. 3. Carbon emissions from liquid slurries and processed manures: (A) Methane (CH_4) and (B) Carbon dioxide (CO_2). Treatments with similar letters (a, b, and c) at each farm did not show statistical significant difference at the $\alpha = 0.05$ level, ANOVA was ran separately for each farm. *DS1 was removed for the field portion of the study, and was not applied to experimental plots.

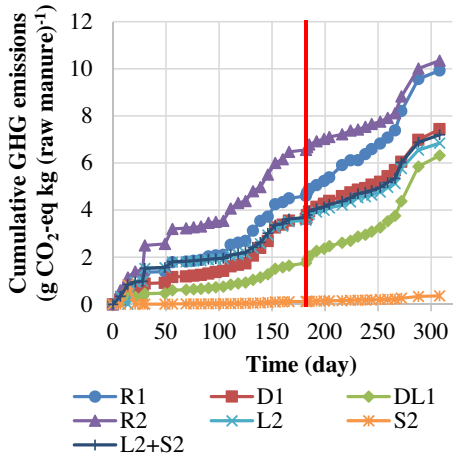

Fig. 4. Cumulative greenhouse gas emissions across storage and field stages of the study. Vertical red line indicates date manure was applied to the field separating the storage study from the field study. (For interpretation of the references to color in this figure legend, the reader is referred to the web version of this article.)

the end of the study suggesting a consistent emission rate when manure is incorporated.

Digested manure, D1, had significantly less (25%) GHG emissions compared to R1 over the entire study period (storage and land application) (Fig. 5). Amon et al. (2006) also found a GHG emissions reduction from digestion following manure storage and application, the magnitude of the reduction was much greater at 59%. Though this previous study was conduted over a shorter time period with no replication, this highlights the range of variability in these experiments. One factor that may directly impact the emissions is the performance of the digester itself, where the level of degradation and carbon capture would greatly impact the downstream mitigation potential. The level of variability supports the need for greater mechanistic understanding to improve predictive models, while also the need to develop parameters to ensure digesters are reaching their potential to remove carbon.

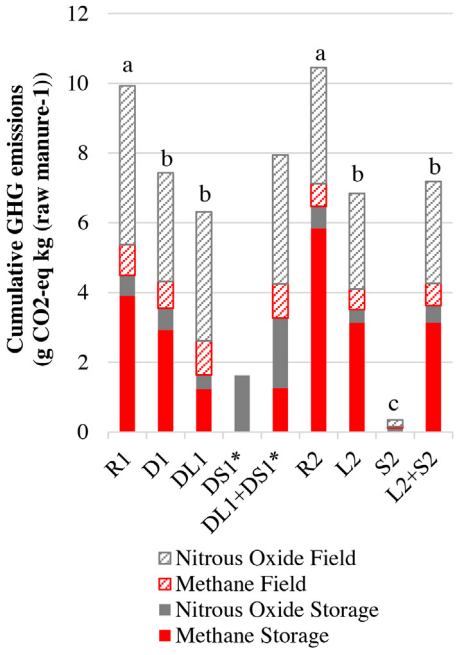

Fig. 5. Greenhouse gas emissions from raw slurries and processed manures proportioned by gas contributing and period of the study. Treatments with similar letters at each farm indicate no statistical difference at the $\alpha = 0.05$ level (ANOVA was ran separately for each farm). *DS1 was removed for the field portion of the study, and was not applied to experimental plots.

With or without processing, the majority of the total GHG contributions from slurry and liquid storage were from CH_4 emissions and following land application were from N_2O (Fig. 5). When analyzing storage independently, D1 had a 21% reduction in total GHG emissions from R1 during the storage portion of the study. Separation did not further reduce cumulative GHG emissions from storage following digestion due to the increased emission of N_2O from the digested solids during storage. For separation alone, there was a significant reduction (44%) in the total GHG emissions over the entire study from R2 to L2 + S2 because storage of the solids did not increase N_2O emissions enough to negate CH_4 mitigation. These results are similar to Amon et al. (2006) which measured a reduction of 37% and contrary to a previous laboratory study by Dinuccio et al. (2011) which concludes that separation of manure increased GHG emssions by 11% during storage and land application. The volatile solids were lower in the initial content of L2 when compared to R2, similar to Amon et al. (2006), resulting in a reduction in CH_4 emissions during storage as expected. However, Dinuccio et al. (2011) measured an increase in CH_4 emissions from separated liquids as compated to the raw slurry during storage even though the VS decreased in the separated liquid. Differences between the current study and Dinuccio et al. (2011) cannot be explained by the measured study parameters.

No GHG treatment differences existed after application of stored manure. After manure was incorporated, it appears that redox conditions were similar between treatments which resulted in similar emissions (Fig. 5). Overall, the methane emissions from storage were reduced by manure processing by 25%, 46%, and 68% for AD, SLS, and AD + SLS, respectively. However, these reductions from storage were somewhat negated when examing total GHG's to 44% and 27% for SLS and AD + SLS due to N_2O losses from solid storage. It is important to note that the reduction from AD in this study may have been low due to reduced performance in the digester, highlighting the need for proper design and operation to maximize C capture in the digester. In addition, managing solids is critical to reduce N_2O production in storage, where providing aeration can reduce N_2O losses.

3.6. Overall emissions and implications for future reductions

According to an inventory of U.S. GHG emissions and sinks in 2014 the dairy manure management emitted 35.5 MMT CO_2-eq of the 574.1 MMT CO_2-eq from agriculture (USEPA, 2016). Dairy manure management is defined by the USEPA as the treatment, storage, and transportation of livestock manure and estimates do not include CO_2. CH_4 accounted for 90% of the 35.5 MMT CO_2-eq from dairy manure management. Based on the results from this study, AD and immediate incorporation of manure following application results in a 25% reduction in CH_4. Therefore, if AD was incorporated at all dairies in the U.S., this would result in a reduction in ~7.2 MMT CO_2-eq. Incorporating AD and SLS further increased the reduction in CH_4 emissions to 40%. Extrapolating these results to all U.S. dairies increased the reduction to ~12.8 MMT CO_2-eq. While using large assumptions concerning manure, these estimates provide a basic understanding of the potential mitigation.

Ammonia loss during storage was the major contributor to losses of nitrogen (Table 3). Digestion increased the amount of ammonia lost in storage due to an increased concentration of ammoniacal nitrogen (Table 3). However, separation following digestion reduced nitrogen losses during storage and the first growing season following land application. Incorporation of SLS following digestion can reduce the ammonia losses in storage, but

the ammonia losses from storage of the digested and separated manure is still greater than the raw manure alone. In practice, it is likely that the solid manures will not be stored for as long as liquid manures, which may further mitigate this practice. However, other land application methods which do not immediately incorporate manure may further increase ammonia losses (Rotz et al., 2014a,b; Webb et al., 2010). Separation alone did show a trend in reduction but was not statistically significant in this study.

Emissions of NH_3 from dairy manure in the contiguous U.S. including emissions from housing, storage, and land application is estimated to be 370 Gg NH_3 per year from 2005 to 2008 (Paulot et al., 2014). Simulated NH_3 emissions from housing, storage, and field application are 18.2, 9.3, and 38.7 kg per cow from a free stall barn with slurry storage on representative dairy farm in Pennsylvania (Rotz et al., 2014a,b). If we assume that manure is immediately incorporated after broadcast 81% of the NH_3 is reduced (Rotz et al., 2014a,b). Given these results we can assume that 7.35 kg NH_3 per cow is lost during after application and housing accounts for 52% of emissions from the housing, storage, and land application of manure. In this study, AD resulted in an 81% increase in emissions of NH_3 meaning that if AD is implemented at all dairies in the U.S., this could result in an increase of 143 Gg NH_3 emissions per year. This estimate assumes that all dairies in the U.S. are free stall barns with manure storage with no cover and that manure applied is immediately incorporated. Given similar assumptions if AD and SLS is implemented at all dairies in the U.S. this would result in an increase of only 57 Gg NH_3 per year.

3.7. Carbon dioxide and carbon cycling

As expected, there are significant losses of carbon in the form of CO_2 during anaerobic storage of manure slurry and liquid. While CO_2 is a large source of GHG emissions from manure as found here and in many other studies (Dinuccio et al., 2011; Hao et al., 2004; Pattey et al., 2005), these emissions are considered to be recycled as part of the carbon cycle that takes places through photosynthesis during the production of crops that are fed to the cows. However, emissions of CO_2 are important as they for evaluation of the carbon cycling within the systems which is critical to mitigation and management strategies. Overall, the objective of manure processing is to reduce the carbon lost as CH_4 while that may increase the carbon lost as CO_2.

Digestion significantly reduced not only the cumulative CH_4 emissions during storage, but also the cumulative CO_2 emissions following digestion (Fig. 3B). However, C captured in the digester can be assumed to be released as CO_2 following combustion. Carbon dioxide emissions during storage for D1 and DL1 were 50% and 67% less than R1, respectively. Both D1 and DL1 had statistically lower initial total C than R1 due to losses during the digestion process with 30% and 48% less C content ($p < 0.1$ and $p < 0.01$, respectively). Emissions of CO_2 per gram of initial C from the entire study period were statistically similar between treatments, indicating that C content was the main driver of CO_2 emissions. DL1 + DS1 had a 19% increase in CO_2 emissions when compared to D1 during storage, which were mostly attributed to the solids portion. This solids fraction had a greater carbon content and the storage was likely more aerobic, both of which are drivers for C to be lost as CO_2 emissions as opposed to CH_4 for solid manure. Separation at farm 2 however reduced cumulative CO_2 emissions as L2 + S2 was 21% lower when compared to R2 during storage, but this reduction was not statistically significant as there was large standard deviation in R2. Although the CO_2 emissions from the solid fraction during storage are less than the CO_2 emissions from the separated liquid fraction at both farms, the solids are the main driver for the net change in CO_2 during storage. The majority of carbon was lost during the storage of manure and was emitted as CO_2 (Table 2).

Manure processing using AD or SLS was able to reduce the carbon lost during manure storage and after one growing season following field application. Digested manure had a reduced amount of initial C (due to the captured C during the digestion process) and had significantly less C loss from storage and application (44%) than their respective raw manures (Table 2). However, it is important to consider the amount of carbon lost during anaerobic digestion to determine its effect on C. The separated liquids DL1, and L2 also had significantly less C loss (58%, and 43%, respectively) than their respective raw manures over the entire study span. The combined C emissions from the L2 and S2 was less than R2 from the entire study span, indicating that separation was effective in reducing carbon losses from storage and land application, although this was not statically significant. Manure processing of AD and SLS was able to reduce the total C lost through the system for the time period of the study. The ratio of C lost as CH_4 and CO_2 remained consistent, meaning that reductions of CH_4 did not result in short increases in CO_2. This suggests that these manure processing systems avoid short term losses of C, which will likely be lost as biotic CO_2 emissions from the soil over a much longer period of time (Table 2).

Table 2
Carbon balance for all treatments during the study. Farm 1 raw manure (R1), farm 1 digested manure (D1), farm 1 digested separated liquid (DL1), farm 1 digested separated solids (DS1), farm 2 manure (R2), farm 2 separated liquid (L2); farm 2 separated solids (S2).

4. Conclusions

AD significantly reduces emissions of CH_4 from storage (25%) resulting in an overall reduction of GHG emissions. SLS reduced CH_4 emissions from storage by 46% alone and by an additional 43% following digestion (total CH_4 reduction in storage of 68% for AD + SLS). This indicates that SLS has a greater mitigation potential for methane in storage than AD, but this likely varies highly depending upon the digester performance. However, combining AD and SLS does not further reduce total GHG emissions from storage than AD alone as anaerobically stacking digested solids increased emissions of N_2O negating abatement of total GHG. AD could also significantly increase NH_3 emissions from manure storages if manure covers are not implemented, although combing AD and SLS could reduce the amount of NH_3 lost following digestion.

In brief

Biomethane and biogas have emerged as cleaner alternatives for natural gas, as they generate fewer greenhouse-gas emissions. However, their production and distribution can still result in methane emissions, the magnitude of which remains unclear. Here, we evaluate methane emissions throughout the biomethane and biogas supply chains and show that emissions are greater than previously estimated. The digestate stage generated the most CH_4, and 62% of total emissions were released by just 5% of emitters.

Highlights

- The biomethane and biogas supply chain may emit up to 18.5 Tg CH_4 per year
- Biomethane and biogas emit much less CH_4 than oil and natural gas
- CH_4 loss rates in biomethane and biogas supply chain exceed those in oil and natural gas
- The top 5% of emitters account for 62% of CH_4 emissions

SCIENCE FOR SOCIETY An immediate shift away from coal and oil for energy is necessary to limit rising temperatures but is challenging due to energy needs, particularly in areas like heating and cooling that require substantial energy supply all year round. Natural gas is presently being used as a bridging fuel. It delivers the same performance as coal and oil but has lower CO_2 emissions. However, natural gas releases methane (CH_4), which is a more powerful warming agent than CO_2. Biomethane and biogas have emerged as strong candidates to replace gas and lower CO_2 and CH_4 emissions. However, these replacement fuels are not CH_4 emission free. Indeed, CH_4 is released at various points during production and distribution, but a thorough understanding of where, when, and how much CH_4 is released remains absent. A synthesis and analysis of existing biomethane and biogas CH_4 emission data reveal that CH_4 emissions throughout the supply chains have been underestimated. The majority of CH_4 comes from just a few super-emitters and mainly at the digestate stage. Mitigating CH_4 throughout biomethane and biogas supply chains is urgently needed if we are to limit global warming to 1.5°C.

SUMMARY

Although natural gas generates lower CO_2 emissions, gas extraction, processing, and distribution all release methane, which has a greater global warming potential than CO_2. Biomethane and biogas that use organic wastes as a feedstock have emerged as alternatives to natural gas, with lower carbon and methane emissions. However, the extent to which methane is still emitted at various stages along biogas and biomethane supply chains remains unclear. Here, we adopt a Monte Carlo approach to systematically synthesize the distribution of methane emissions at each key biomethane and biogas supply chain stage using data collected from the existing literature. We show that the top 5% of emitters are responsible for 62% of emissions. Methane emissions could be more than two times of greater than previously estimated, with the digestate handling stage responsible for the majority of methane released. To ensure the climate benefits of biomethane and biogas production, effective methane-mitigation strategies must be designed and deployed at each supply chain stage.

INTRODUCTION

As we move further into the 21st century, energy systems must move away from fossil fuels and grow in renewable energy capacity if Paris Agreement temperature targets are to be met. However, due to challenges in adopting low-carbon technologies, certain areas of global energy systems are difficult to decarbonize. These include heavy industry, transport, and heating and cooling systems, which together account for a significant portion of carbon dioxide (CO_2) emissions.[1] Natural gas has therefore been used as an important alternative fuel, which can offer large-scale energy supply, especially for domestic space heating and hot water needs, electricity generation, and industrial applications, with much lower CO_2 emissions compared with oil and coal. Although replacing oil and coal with natural gas reduces CO_2 emissions, fugitive emissions from the supply chain of natural gas—gas extraction, processing, and distribution—can all release CH_4. Around 39.6 million tonnes of CH_4 were emitted in 2021,[2] representing 61% of oil and gas emissions and 30% of total-energy-sector CH_4 emissions. Since CH_4 has a much stronger global warming potential than CO_2 and is currently responsible for at least one-quarter of global warming, there are strong calls for natural gas use to be reduced by at least 35% by 2050 and 70% by 2100 relative to 2019;[3]

therefore, alternative clean-energy methods are vital to replace natural gas to limit global warming to 1.5°C.

An alternative method of decarbonizing natural gas is via replacing it with biomethane or biogas, which is a mixture of gases (mostly CH_4 and CO_2) produced from biodegradable materials. Biomethane and biogas production and use have been put forward as part of mitigation efforts,[4] with up to 37 exajoule (EJ)/year of biomass-based gases in Intergovernmental Panel on Climate Change Special Report on Global Warming of 1.5°C (IPCC SR1.5C) scenarios,[5] which limits temperature rises to below 2°C. The International Energy Agency (IEA)[6] reported that global biomethane and biogas production could satisfy nearly 20% of global gas demand if its sustainable potential was fully utilized.[6] Because biomethane is similar to natural gas, it can be easily stored and injected into the existing natural gas infrastructure, potentially providing reliable and affordable energy.[7] At the time of writing, Europe is the world leader in biomethane production by upgrading biogas, followed by the United States, China, and Canada.[8] According to the World Biogas Association (2019), 700 biogas-upgrading plants are operating worldwide, with 195 in Germany (the largest producer), with biogas currently dominating biomethane production. Biomethane and biogas production are expected to grow further, with demand predicted to grow 9-fold by 2040 compared with 2018 levels,[6,9] driven by increases in the volume of organic waste generated by modern societies, changes in waste practices, and the phasing out of fossil fuels aimed at reducing greenhouse gas (GHG) emissions and meeting government targets. Given this host of commitments, investments, and developments, biomethane and biogas could be crucial in helping to establish a clean, reliable, and affordable global energy system.

However, large quantities of CH_4 can still be emitted from the biomethane and biogas supply chains, including digestate handling, anaerobic digesters, upgrading units, feedstock storages and transmission, and storage and distribution stages.[4] CH_4 is a relatively short-lived GHG but has a global warming potential (GWP) 27.2 ± 11 times larger than CO_2 over a 100-year horizon and 80.8 ± 25.8 times larger over a 20-year time horizon for biogenic sources.[10] The importance of reducing CH_4 emissions to meet Paris Agreement[11] targets has been demonstrated by Rogelj et al.,[12] as it is an important GHG in terms of potential overshooting of Paris Agreement targets, where warming exceeds "well below 2°C" and then returns to the target level by 2100,[10] leading to potential tipping points in physical and socio-economic systems. The IPCC (Intergovernmental Panel on Climate Change) Sixth Assessment Report (AR6) (Working Group III)[13] highlighted CH_4 as playing a significant role in determining whether or when 1.5°C is achieved, as reducing CH_4 emissions will offset global temperature increase much more quickly than CO_2, due to its relatively short lifetime and higher GHG potency. The AR6 report also noted that reductions to CH_4 emissions will need to occur more rapidly than CO_2 and that reducing CH_4 (and other non-CO_2 GHG) emissions is essential for lowering warming.[13] As the AR6 scenarios predict biomethane capacity to increase by up to 200-fold between 2020 and 2050,[14] understanding where CH_4 emissions occur and how much is emitted is crucial.

There are some emissions-measurement studies to date focusing on specific biomethane facilities,[4,15–22] which have measured on site (measurement of emissions at each individual point source) and off site (measurement of emissions based on observations made away from the site). These can also be referred to as bottom-up (on-site) and top-down (off-site) studies. These have found that emissions from biomethane facilities can be up to 97 kg h^{-1} CH_4.[4,16–24] However, a comprehensive evaluation by characterizing the distribution of CH_4 emissions at each biomethane and biogas supply chain stage remains unclear.

Here, we bring together the published emissions data from CH_4-measurement studies to assess and synthesize the distribution of emissions from each supply chain stage in order to characterize the emissions profile of the biomethane and biogas supply chain (see experimental procedures and Figure S1 for the selected supply chain route). A Monte Carlo aggregation examines the distribution of supply chain emissions. This allows for the emission profile of biomethane and biogas supply chains to be characterized. We find that, while the biomethane and biogas supply chain emits less CH_4 than the oil and natural gas supply chain, the emission rate is higher. Furthermore, we find that 62% of cumulative emissions are released by just the top 5% of emitters. We also find that methane emissions could be more than two times higher than previously estimated, and the digestate-handling stage contributed to the largest CH_4 emissions along the supply chain. Our results will allow for a greater understanding of how to improve the sustainability of biomethane and biogas production by providing plant operators, investors in the supply chain, and policymakers with information on where improvements can be made in biomethane and biogas supply chains to reduce CH_4 emissions, as well as whether existing or proposed CH_4 regulations are sufficient or need to be revised.

RESULTS

Method summary

To assess overall supply chain emissions, the biomethane supply chain is divided into five major stages: (1) feedstock; (2) biogas production; (3) biogas upgrading; (4) transmission, distribution, and gas storage; and (5) digestate storage. This study was compiled from several published studies and the data from on-site (taken at each individual emission source) and off-site measurements (reported for the entire site). The kernel density estimation (KDE) function was used to assess the characteristics of the data distribution gathered from individual sources for each stage of the supply chain. Following that, a Monte Carlo simulation was performed to estimate total supply chain emissions, which were then compared with the off-site emissions reported from whole-site measurements in previously published studies (see the experimental procedures for further details).

Total supply chain emissions

The cumulative distribution of the supply chain CH_4 emissions is shown in Figure 1A. Median and mean emissions are 40.0–42.3 g $CO_{2\text{-eq.}}/MJ_{HHV}$ (41.1–41.3 at the 95% confidence interval [CI]) and 51.4–52.7 g $CO_{2\text{-eq.}}/MJ_{HHV}$ (52.2–52.4 at the 95% CI), respectively, with a 5th percentile of 11.0–16.3 g $CO_{2\text{-eq.}}/MJ_{HHV}$ (15.6–15.7 at the 95% CI) and a 95th percentile between 118.2 and 144.0 g $CO_{2\text{-eq.}}/MJ_{HHV}$ (131–133 at the 95% CI) using

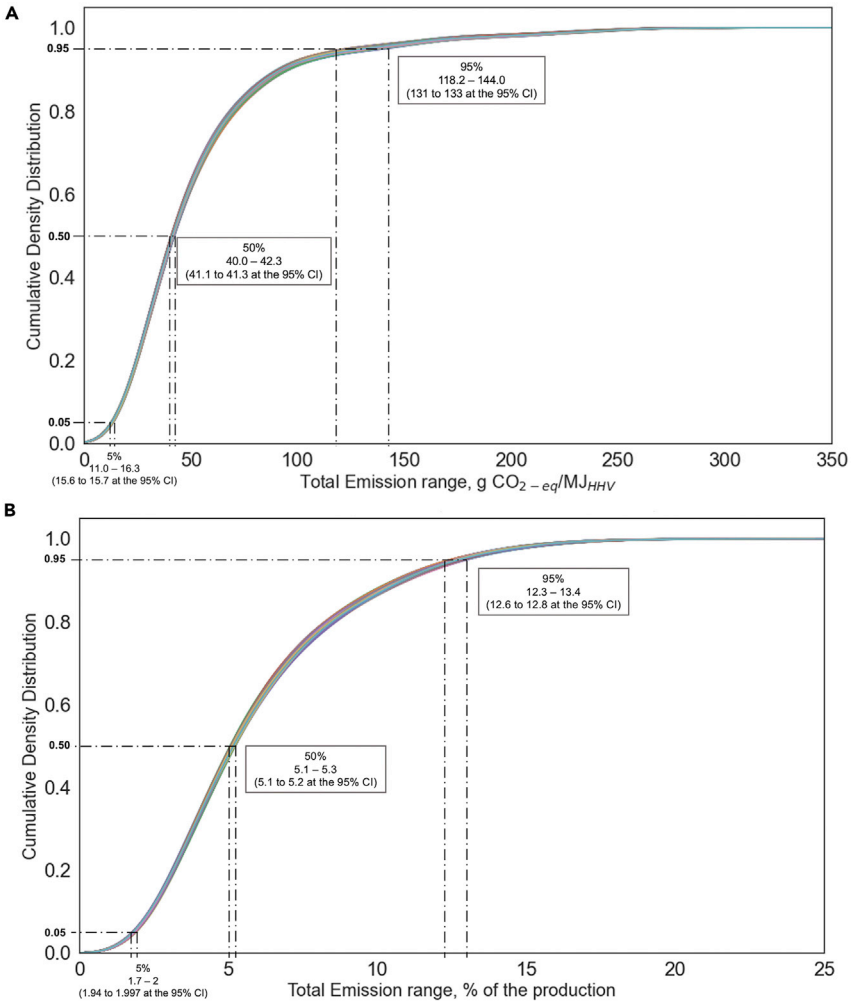

Figure 1. Cumulative distribution of CH_4 emissions from the total supply chain

(A) Cumulative distribution of total supply chain CH_4 emissions for the 10,000 Monte Carlo runs and 100 curves described in the experimental procedures, expressed as g $CO_{2\text{-eq.}}/MJ_{HHV}$.

(B) Cumulative distribution of total supply chain CH_4 emissions for the 10,000 Monte Carlo runs and 100 curves, expressed as percentage of total CH_4 production.

The range of 5th, 50th, and 95th percentile estimates are shown as dotted black lines. CI: confidence interval.

GWP_{100} values. Each curve defines the cumulative distribution for a single Monte Carlo simulation and shows that total supply chain emissions range from 2.5 to 343 g $CO_{2\text{-eq.}}/MJ_{HHV}$. The emissions distribution is highly upward skewed (Figure 1A), which is indicative of disproportionately high emitting sites referred to as "super-emitters" (see the identification of super-emitters section for details). Our findings are consistent with those observed for oil and natural-gas supply chains.[25–30] Using global biogas and biomethane production of 35 megatonnes of oil equivalent (Mtoe) (1.47×10^{12} MJ) in 2018,[6] our model-based estimate of 2018 biomethane supply chain emissions may account for up to 18.5 teragram (Tg) CH_4 per year (6.4–7.8 Tg CH_4 year^{-1} at the 95th percentile and an average of 2.8–2.9 Tg CH_4 year^{-1}), which is more than two times greater than the International Energy Agency's (IEA's) estimate of CH_4 emissions from bioenergy (9.1 Tg in 2021).[2] Our estimate of global biogas and biomethane CH_4 emissions is significantly lower than in the global oil and natural-gas supply chain (82.5 Tg in 2021);[2] on the other hand, it is comparable to the production segment of the US oil and natural-gas supply chain (6.1–7.1 Tg year^{-1})[31] based on site measurements.

The cumulative distribution of emissions as a percentage of total CH_4 produced is shown in Figure 1B. The 5th percentile is 1.7%–2.0% (1.94%–2.0% at the 95% CI) of CH_4 production, and the 95th percentile is 12.3%–13.4% (12.6%–12.8% at the 95% CI) of total gas production. The ranges in minimum, median, mean, and maximum values were fairly consistent across all estimates (Figure 1). While the low and median estimates are nearly identical, the disparity between biomethane and natural gas varies widely in the highest estimates. The median ranged from 5.1% to 5.3% (5.1%–5.2% at the 95% CI), with mean emission rates of 5.90%–6.04% (5.9%–6.0% at the 95% CI) of total CH_4 production, which is higher than natural gas (0.8%–2.2% of CH_4 production).[25,26] Rutherford et al.[31] found CH_4 emissions in the oil and natural-gas-production segment to be 1.3% (1.2%–1.4% at the 95% CI), which is significantly lower than our findings. On the other hand, despite declining gas production, one of the highest reported CH_4 emissions from oil and gas production (Uinta Basin from a multi-year record of in-site observations) reveals a higher emission rate than our results (6%–8%).[32] Although emissions from the biomethane supply chain are comparable to oil and natural-gas production in terms of Tg CH_4 year^{-1}, the production-normalized emission rate is considerably higher. This could be due to a variety of factors, including poorly managed production facilities; a lack of attention to the biomethane industry resulting in lower investments for modernization, operation, and monitoring; and employment of highly skilled plant operators[16,21] when compared with oil and natural gas. In addition, poor design and management of feedstock and digestate storage units[33] as well as a limited interest in infrastructure emissions may result in higher emission rates compared with the amount of gas produced. Because oil and natural-gas supply chains have been primarily operated by large companies for decades, they have invested more in leak detection and repair.[34,35] On the other hand, given the growth in biomethane generation due to national decarbonization strategies, more urgent efforts are also needed for the biomethane supply chain to address not only CH_4 emissions but also the sustainability of biomethane.

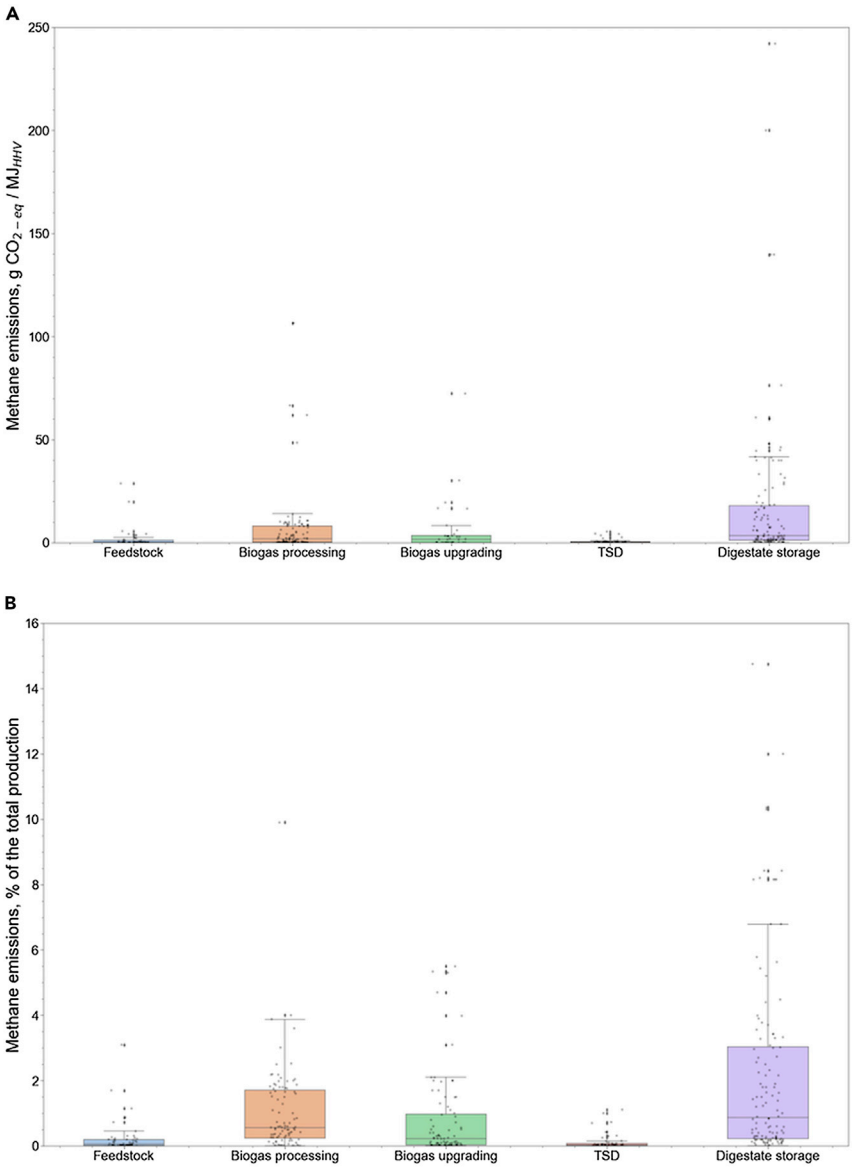

Figure 2. Literature CH_4 emissions from different stages of biomethane supply chain

(A) Emissions range of feedstock (n = 49), biogas processing (n = 100), biogas upgrading (n = 35), TSD (n = 44), and digestate storage (n = 119) stages in g $CO_{2\text{-eq.}}/MJ_{HHV}$.

(B) Emissions range of feedstock (n = 52), biogas processing (n = 95), biogas upgrading (n = 84), TSD (n = 48), and digestate storage (n = 120) stages in terms of total CH_4 emissions as a percentage of the total gas production rate.

Individual estimates are shown as circles in the same color at each stage of the supply chain, with median and 25th and 75th percentile boxes. Sample sizes for each stage are demonstrated in the Figure 3.

Identification of super-emitters

A small proportion of facilities or equipment with disproportionately large emission rates are labeled super-emitters,[36,37] causing the heavy-tailed distribution (see Figure S4). A small number of high emitters may cause under- or overestimations of emissions rates[38] if they have intermittent emissions patterns, insufficient process equipment usage, or inadequate operations and maintenance strategies. In this study, super-emitters have been investigated at various stages across the supply chain, including feeding systems; substrate storage; runoff ponds; pressure relief valves on the anaerobic digesters and gas holders; exhausts and aeration lines of upgrading units; ventilation of units, such as compressors or closed digestate tanks; open digestate storage; and flaring. Within the heavy-tail distribution (Figures 1A and 1B) and the boxplot of each stage's emissions (Figure 2), the mean emission rate is higher than the median because of super-emitters (see Table S1 for details). Since we lack information on on-site CH_4 sources, we identify them as the top 5% of highest emissions based on the cumulative density function of CH_4 emissions, parallel to natural-gas production sites.[29,36,39] The highest 5% of total emissions (199–224.8 g $CO_{2\text{-eq.}}/MJ_{HHV}$) account for 62% (CI: 58%–66%) of cumulative emissions, with a threshold of 211.9 g $CO_{2\text{-eq.}}/MJ_{HHV}$. The characteristics of super-emitters in the biomethane supply chain are similar to those of super-emitters in the oil and natural-gas supply chain (the largest 5% of leaks contribute to 50%–60% of total emissions).[29,36] Since super-emitters are unlikely to remain constant over time, continual monitoring will be required to detect intermittent emission patterns or unpredictable leaks from the biomethane supply chain. Future work is necessary to understand the characteristics of individual super-emitter sites in the biomethane supply chain. The efficiency of mitigation efforts could be improved by investing in the underlying cause of preventable operational conditions at a component level.[30]

Contribution of each supply chain stage

The contribution of each stage of the biomethane supply chain is illustrated in Figure 2A in g $CO_{2\text{-eq.}}/MJ_{HHV}$ and as a percentage of total production in Figure 2B. The distributions are almost identical. Emissions are mainly from digestate storage, followed by production and upgrading stages. Similar results were observed by Reinelt et al.,[17] where the highest emissions are from open digestate storage and pressure-release valves. Similarly, Alvarez et al.[39] found production and gathering units to be the main emission source in the US oil and natural-gas supply chain. Overall, the lowest emissions are exhibited in the transmission, storage, and distribution (TSD) stage, similar to the US oil and natural-gas supply chain.[39]

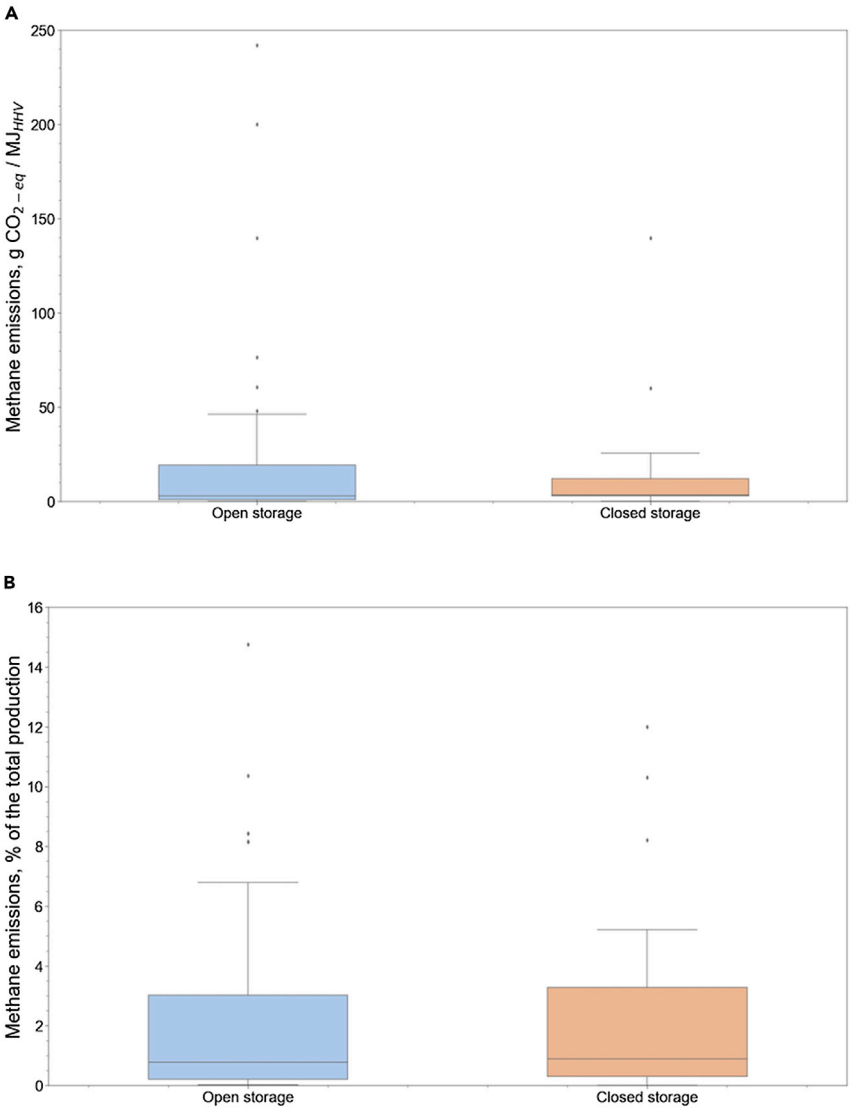

Figure 3. Literature CH_4 emissions of open and closed digestate storage

(A) Emissions from digestate handling from open (n = 98) and closed (n = 21) storage tanks in g $CO_{2\text{-}eq.}/MJ_{HHV}$.

(B) In terms of the percentage of total biomethane produced, illustrating emissions from the open (n = 95) and closed (n = 25) storage tanks.

Closed tank emissions originate mainly from leaks of covered material and ventilation of stockpile building.

Of particular note here is that the digestate storage stage is a significant source of CH_4, ranging between 0.05 and 242.1 g $CO_{2\text{-}eq.}/MJ_{HHV}$ (Figure 2A) or 0.005% and 14.8% of the total biomethane produced (Figure 2B). Sources of emissions are open or covered digestate (liquid and solid) storage tanks and lagoons. The emissions from digestate handling, such as post-composting processes, application of digestate, thickening exhaust, dewatering units, and leaks from centrifuges, were excluded from the biomethane supply chain in this study. Our analysis revealed that CH_4 emissions from this stage are 23% higher than previously reported,[40] while they still form a substantial portion of previous studies.[19,40]

The biogas production stage is the second biggest emission source, ranging from 0.002 to 106.5 g $CO_{2\text{-}eq.}/MJ_{HHV}$ (Figure 2A) or 0.001% to 9.9% of CH_4 production (Figure 2B). Biogas-production emissions are mainly from the anaerobic digester and hygienization tank. Hygienization tanks represent a relatively small fraction of the emissions from this stage. Emissions from the anaerobic digester are highly variable, depending on fugitive emissions from different cover types and control of venting from pressure-release valves. In addition, Zeng et al.[41] found that the fermentation temperature and quality of the feeding material have an effect on the CH_4 emissions from anaerobic digesters. Following biogas production, estimates of emissions from biogas upgrading are 0.002–72.4 g $CO_{2\text{-}eq.}/MJ_{HHV}$ (Figure 2A) or 0.001% to 5.5% of CH_4 production (Figure 2B), which are slightly higher than what was reported by Dumont et al.[40] The emissions from the biomethane production stage arise from the exhaust or aeration of units, ventilation ducts, booster pumps, safely valves on upgrading facilities, water or chemical scrubbers, and membranes.

In addition, feedstock emissions, resulting from fugitives and vents from substrate storage, are the fourth highest contributor to the supply chain, accounting for 0.0003 to 28.8 g $CO_{2\text{-}eq.}/MJ_{HHV}$ (Figure 2A) or 0.0003% to 3.1% of the total CH_4 production (Figure 2B), and represent the smallest proportion of total supply chain emissions. Higher emissions are associated with substrate storage. Dumont et al.[40] reported a larger range in CH_4 emission (0.2%–0.5% of CH_4 production) for feedstock storage.[40] However, their results were based on a smaller dataset than ours, and emissions may have reduced through technology improvements since their study was published.

Digestate-handling approaches

As discussed above, digestate storage is the largest emission source in the biomethane supply chain. This is because of the accumulation of organic material, which leads to CH_4 production from fermentation. According to Döhler et al.,[42] digestate storage may account for nearly 27% of global $CO_{2eq.}$ emissions from anaerobic digestion processes. How digestate is handled has a major impact on emissions, with open digestate storage tanks and lagoons emitting more than closed tanks similar to the results from Paolini et al.[33] (Figure 3). The residual gas potential, digestate temperature, substrate amount, level of filling, and meteorological conditions all have a significant influence on the emission rate from open digestate storage tanks

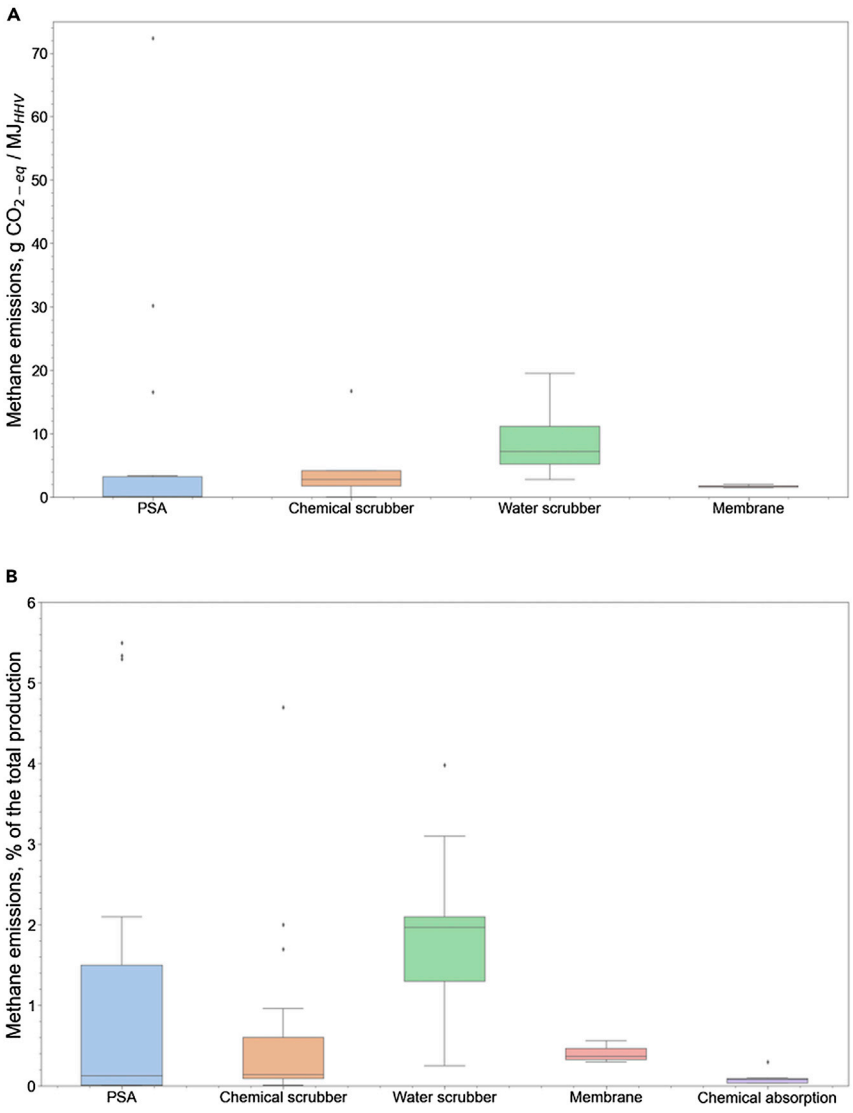

Figure 4. Literature CH_4 emissions from different biogas-upgrading technologies

(A) Emissions from biogas-upgrading technologies in g $CO_{2\text{-eq.}}/MJ_{HHV}$, pressure swing adsorption (PSA) with activated carbon filters (n = 22), water scrubber (n = 4), chemical scrubber (n = 5), and membrane (n = 4).

(B) Emissions from upgrading biogas technologies in terms of the percentage of total biomethane produced, with PSA with activated carbon filters (n = 30), water scrubber (n = 9), chemical scrubber (n = 25), chemical absorption (n = 14), and membrane technologies (n = 6).

Scrubber emissions include chemical (e.g., amine) and water scrubber emissions.

and lagoons.[15,19,43,44] Figure 3 clearly demonstrates that the closed tanks can still emit CH_4, although emissions from closed tanks can be avoided with improved covering materials, effective design, and regular maintenance. The facilities should consider becoming accredited under the Publicly Available Specification (PAS) 110 standards,[45] which recommend coverage of digestate to diminish emissions. Therefore, we recommend using closed digestate storage with vapor-recovery systems directed to the upgrading unit where economically viable to address emissions from this stage. Targeting reductions in digestate-handling emissions provides the greatest environmental improvements, though it is noted that detection and mitigation strategies would require additional expense and regulation.

Impact of biogas-upgrading technologies

Upgrading biogas to biomethane can cause significant emissions. The literature provides scant data on specific upgrading technologies, though available evidence shows that membrane filters and chemical absorption leads to lower emissions than pressure swing adsorption (PSA) and water and chemical scrubbers (see Figures 4A and 4B). Therefore, initial indications are that chemical absorption technology is the best available technology for upgrading to reduce CH_4 emissions, which is the line with previously reported values.[46,47] PSA and water scrubber utilization should be avoided, though more measurements should be conducted.

Total supply chain emission estimates versus whole-site mobile measurements

Alongside the on-site (aggregation of component-based emission) Monte Carlo approach described above, whole-site (off-site) measurements are a useful benchmark. In the literature, CH_4 emissions from 792 whole-site measurements varied between 0.1 and 483 g $CO_{2\text{-eq.}}/MJ_{HHV}$, with an average of 51.7 and a median of 24.6 g $CO_{2\text{-eq.}}/MJ_{HHV}$ (see Figure 5A). This is a larger range with lower median and higher estimate of upper limit than our Monte Carlo simulation of on-site measurements. While the mean of the Monte Carlo runs (51.4–52.7 g $CO_{2\text{-eq.}}/MJ_{HHV}$) and whole-site measurements (51.7 g $CO_{2\text{-eq.}}/MJ_{HHV}$) are comparable, the median of the Monte Carlo runs (40.0–42.3 g $CO_{2\text{-eq.}}/MJ_{HHV}$) are greater than the whole-site measurements (24.6 g $CO_{2\text{-eq.}}/MJ_{HHV}$) due to the heavy-tailed distribution of the Monte Carlo runs. Before running the Monte Carlo simulation, the emissions probability density function of each stage is identified to establish a good fit. The heavy-tailed distribution is due to the presence of super-emitters in each supply chain stage in the Monte Carlo runs, while whole-site emissions data did not exhibit this heavy tail.[48] However, super-emitters are certainly observed in the whole-site measurements and the maximum emission is greater than in the Monte Carlo runs, but these are insufficient in quantity and magnitude to raise the median above the mean. This discrepancy between the distribution of whole-site measurements and that observed in the Monte Carlo approach (i.e., from aggregation of measurements from each stage) is

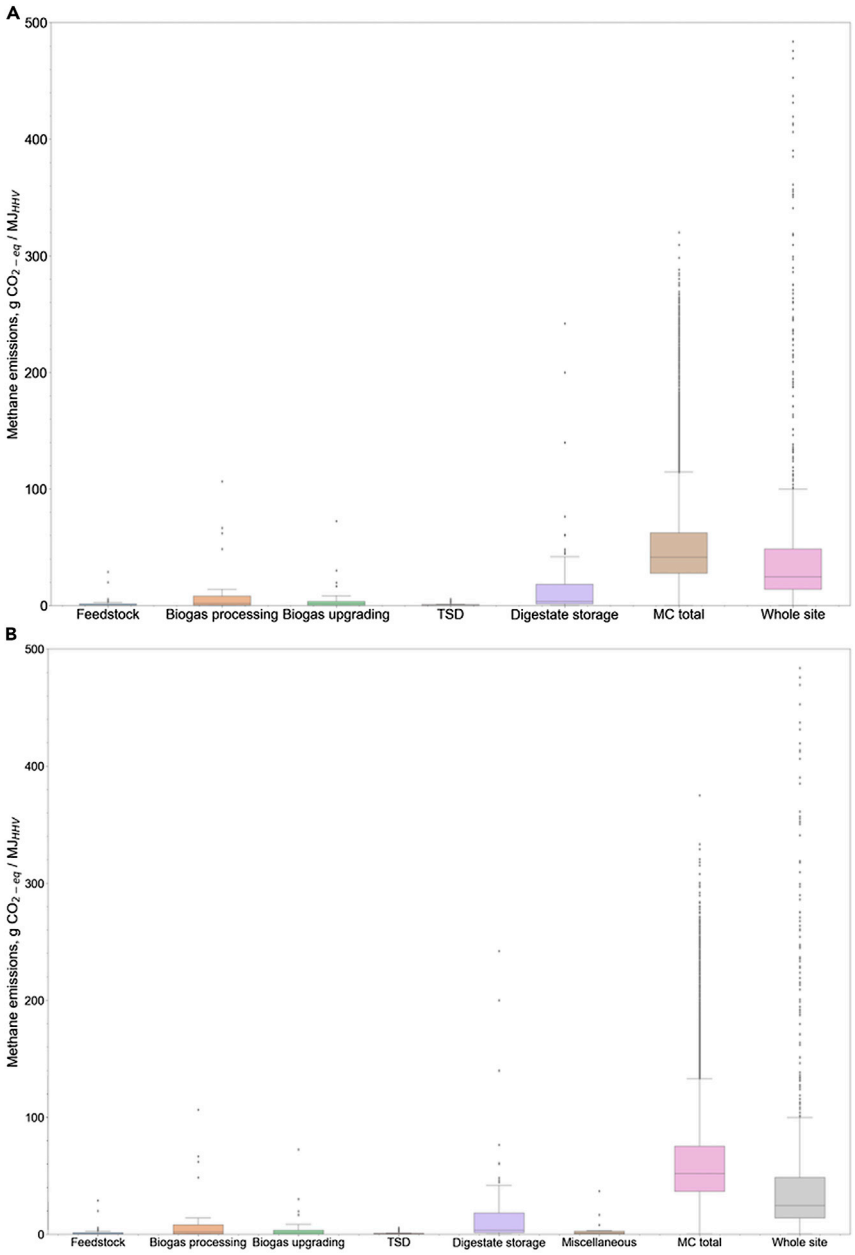

Figure 5. Each stage of emissions with the whole-site measurements and MC runs

(A) Literature emissions range for feedstock (n = 49), biogas processing (n = 100), biogas upgrading (n = 35), TSD (n = 44), and digestate storage (n = 119) stages with whole-site measurements (n = 792) and 10,000 Monte Carlo runs (MC total) with respect to g $CO_{2\text{-eq.}}/MJ_{HHV}$.

(B) Miscellaneous sources (n = 19) were added as an additional stage emission and MC total was reassessed to compare with whole-site emissions (off-site measurements).

Individual estimates are shown as circles in the same color at each stage of the supply chain, with median and 25th and 75th percentile boxes. Sample size for each stage and whole-site emissions are depicted. The median of the MC run is substantially higher than the medians of the five stages added together because (1) the medians of the derived KDE functions for each supply chain stage are substantially higher than those of the raw data and, (2) in any case, it is not expected that the sum of medians from each supply chain stage necessarily approximates the median of the sum of stages (see the experimental procedures for details).

worthy of further research in the future. A number of factors are known to affect measurements, including meteorological conditions during the survey, duration of measurements, uncertainties in emissions rate calculation models, the presence of super-emitters, and process conditions of facilities.[18] It is also likely to be influenced by miscellaneous sources (see Figure 5B),[19] such as biofilters used for odor reduction, stored solids causing fermentation, emissions from service opening,[19] or leakages located on top of units,[49] which are not quantified by the on-site measurement studies. We combined the miscellaneous sources reported in a few studies[19,23,50,51] and estimated their impacts on total emissions using a Monte Carlo simulation (see Figure S2) after identifying the associated KDE (see the experimental procedures), which impacts the data distribution.

Figure 5B demonstrated that miscellaneous sources could increase total supply chain emissions by 22%. However, it is noted that, because only four studies reported emissions from biofilters and solid separators, more detailed monitoring surveys are required to better understand the impact of miscellaneous emission sources on supply chain emissions. The high leakage rate reported in off-site measurements could also be due to process disturbances or extensive venting and flaring caused by insufficient infrastructure, which results in an intermittent and highly unpredictable emissions pattern that can overestimate or underestimate significant CH_4 sources.[38] The divergence between on-site and off-site measurements is most likely due to abnormal operating conditions resulting in high CH_4 emissions primarily from the production segment,[31] which is consistent with that of oil and natural-gas supply chains.[39] We agree with Zavala-Araiza et al.[52] and Rutherford et al.[31] that increasing on-site, component-level emission data through continuous emission monitoring and effective characterization of emission sources can reduce the uncertainty and divergence between on-site and off-site measurements.

DISCUSSION

Overall, this study showed that the broad features of the biomethane supply chain led to emission profiles similar to those of oil and natural gas, although digestate handling, biogas production, and upgrading are key differentiators. The synthesis of

available data here showed that this leads to lower direct CH_4 emissions than the oil and natural-gas supply chain but much higher CH_4 loss rates than the oil and natural-gas supply chain. This conclusion is pertinent in the context of global efforts to mitigate CH_4 emissions, which to date largely focuses on natural-gas supply chains. It is also pertinent to broaden efforts to mitigate climate change, where CH_4 emissions are increasingly recognized as a key climate forcer. Given the strong potential role of biomethane in Paris Agreement compliant energy futures, best available technology must be applied to detect and reduce supply chain emissions, policy and regulation[53] must consider these emissions more systematically, and a better understanding of the counterfactual life cycle emissions for waste and by-product biomethane feedstocks must be developed. It should be noted that, even if feedstocks are not used to generate biomethane, they may still emit CH_4; in fact, some studies have suggested that treating manure for biomethane production could be a mitigation strategy.[54] We believe that this large amount of CH_4 emissions from the biomethane supply chain, on the other hand, can be avoided by taking appropriate emission identification, detection, measurement, and quantification measurements. It is critical to emphasize that, if biomethane is widely used in the future to achieve decarbonization goals, biomethane supply chain emissions should be avoided in order to achieve net zero goals.

Reflecting on these results with respect to the EU Renewable Directive (RED) 2009/28/EC,[55] it is clear that cutting emissions from digestate handling and gas engines could underpin more sustainable biomethane production. According to an EU report[56] on the sustainability of solid and gaseous biomass used for electricity, heating, and cooling, the GHG threshold for biomethane production is 34.8 g $CO_{2\text{-eq.}}/MJ_{HHV}$,[56] excluding digestate emissions. In contrast, CH_4 emissions from the biomethane supply chain are estimated in this study to range from 2.5 to 343 g $CO_{2\text{-eq.}}/MJ_{HHV}$ and 0.8 to 182 g $CO_{2\text{-eq.}}/MJ_{HHV}$ (18.3–19.5 g $CO_{2\text{-eq.}}/MJ_{HHV}$ for the median and 64–74 g $CO_{2\text{-eq.}}/MJ_{HHV}$ for the 95th percentile) when digestate emissions are excluded (see Figure S3). In view of CO_2 and N_2O (GWP_{100} = 273 ± 130)[10] emissions from biomethane production, total GHG emissions from the biomethane supply chain are likely to exceed this threshold limit unless urgent actions are taken. Given the different lifetimes and GWPs of CO_2, CH_4, and N_2O, future research can focus on integrating emissions across different timescales in order to further expand the impact of the biomethane supply chains on global warming and climate change. Clearly, under these operating conditions and in light of the wide diversity of biogas production pathways, biomethane production may lose its advantages as a clean-energy technology and may jeopardize Paris Agreement targets if used extensively. This study would serve as a guideline for the emission ranges associated with each stage while also recommending appropriate measures for each stage to cut emissions and make progress toward Paris Agreement goals. Therefore, emission-minimizing technologies and techniques and more specific regulations on emissions and leak detection and repair are essential to significantly reduce supply chain emissions. We are also aware of the counterfactual case for what level of CH_4 emissions would occur if the feedstock had not been converted into biomethane. Future studies should focus on counterfactual analyses to assess the GHG credits under various counterfactual scenarios.

Our biomethane supply chain emissions model presented in this study represents the most common technologies used in the industry, but it has some limitations regarding data availability and resolution. Firstly, input data were taken only from measurement surveys, and the sample size is not large enough to determine a probability distribution model for each supply chain. As such, the KDE function was used rather than goodness of fit since the data could not be fitted to certain distribution functions, due to the lack of data and heavy-tailed distribution. Furthermore, much of the literature data were excluded, owing to the use of default emission factors, especially in modeling studies. Secondly, some studies could not be included because they did not report biogas or biomethane production rates despite reporting CH_4 emissions.

The most detailed measurement surveys have been conducted in various regions of Europe and mainly at agricultural plants, so this study substantially reflects European agriculture. Further possible research directions associated with this work include adapting the emissions profiles of theoretical supply chain routes, for example, using life-cycle-assessment tools. Future research should target data collection from various biomethane supply chain routes in other countries to reduce uncertainty in the data and improve size and representativeness of the samples, which can help to identify the most sustainable biomethane production routes. This accumulated database can be used to improve equipment, processes design, and operations that would mitigate CH_4 emissions.

EXPERIMENTAL PROCEDURES

Resource availability

Lead contact

Further information and requests for resources should be directed to and will be fulfilled by the lead contact, Semra Bakkaloglu (s.bakkaloglu@imperial.ac.uk).

Materials availability

This study did not generate new unique materials.

Data and code availability

All original datasets used in this work were made available as part of the publications referenced and described in the text. The Python code used for the Kernel density estimation (KDE) function and Monte Carlo simulation with the data have been deposited at Zenodo Data: https://doi.org/10.5281/zenodo.6550794.

Methodological approach

This study aims to estimate CH_4 emissions from the biomethane supply chain and characterize the emissions sources in the various stages of the supply chain (described in Figure S1). The screening criteria for mobile CH_4 emissions measurements required on-site or off-site direct measurements be reported by the study authors, rather than drawing on experimental, lab-scale, and theoretical studies.

The existing literature reports emission rates in different units, and some studies provide insufficient information to allow for unit conversion. In this study, CH_4 emission estimates were converted into percentage of total production (volume of CH_4 emitted/volume of produced gas) and grams of CO_2 equivalent per megajoule of energy based on higher heating value (HHV). These were chosen to allow for comparisons with the oil and natural-gas supply chain without inferring downstream services. The source emissions were divided by the total expected volume of biomethane that would be generated for energy utilization.

Assumptions were applied to convert published emission rates into metric units. It was assumed that the GWP_{100} of CH_4 is 27.2,[10] with an HHV of

38.1 MJ/m^3 or 55.5 MJ/kg. The average volume percentages of CH_4 in biogas and biomethane were taken as 65% and 95%, respectively, unless otherwise stated in a study. We assumed the CH_4 content is 55% in biogas for manure feedstock. We neglect uncertainty of measurements and GWP_{100} (±11), although measurement uncertainty exists whenever an emissions rate is quantified. Similar to Brandt et al.,[28] we evaluate all emissions at their reported levels and investigate the impact of emissions distribution. GHG emissions other than CH_4, such as CO_2, N_2O, and NH_3, were not included because they are out of the scope of this study. Moreover, CH_4 emissions based on GWP_{20} (80.8) were provided in the Figure S4. The three stages of this study are:

1. Building the emissions inventory
2. Assessing the supply chain emissions model
3. Applying Monte Carlo simulations to produce total emissions ranges.

Emissions inventory

Following systematic reviews of the existing evidence base, 51 papers reporting mobile CH_4 emissions measurements were examined, including academic papers as well as governmental and industry reports (see the supplemental experimental procedures). We utilized the data from mobile CH_4 measurements using on-site leak detection and ground-based remote sensing methods (off site). CH_4 emissions from landfill were excluded because there is a lack of data on the amount of biogas and biomethane generated from landfill-gas-collection system, which is mainly calculated using landfill-modeling tools, and CH_4 emissions depend on CH_4 oxidation rate as well as top soil cover material rather than infrastructure emissions.[57] In addition, we only considered the emissions from wastewater treatment plants with anaerobic digesters. The details of the chosen biomethane supply chain route employed in this study are described in detail in the Figure S1.

Emission inventory data availability is highly variable, owing to variations in the applied methodologies, differing plant design and operation, and insufficient data for each supply chain. Most emissions data were for Europe. Datasets for each emissions source were divided into subcategories, where there was discernible variation between feedstock materials (see Table S1). The stages in the biomethane supply chain are (1) collecting and storing organic materials (feedstock); (2) converting them to biogas under anaerobic conditions (AD); (3) upgrading biogas to biomethane (upgrading); (4) transportation, gas storage, and distribution of generated gas (TSD); and (5) digestate storage.

Feedstock storage

Any biodegradable material, such as agricultural residues, maize, crops, sewage sludges, or food and drink waste, utilized in anaerobic digestion is called feedstock. The yield of biogas from a specific feedstock can vary based on the dry-matter content, residence time in the digester, and feedstock purity.[58] Feedstock transported from a third party to the production facility is stored in the facility and pre-treated before being sent to the biogas-production stage. This stage covers four major components: runoff ponds, screw conveyor, mixing tank (homogenization tank), and substrate storage. Substrate storage tanks and biomass-receiving units, such as feedstock piles, runoff ponds, screw conveyors, and mixing (homogenization) tanks, are the main sources of emissions, although few studies have investigated emissions from this stage.[15,17,19,22,46,49,59–61] Feeding system emissions are included in substrate storage emissions (see Table S1). These emissions are mainly fugitives, predominantly from open storage tanks and feeding units.

Biogas production

The physically treated material is pasteurized and delivered to an anaerobic digester to generate biogas. The CH_4 concentration in the biogas depends on the type of digestate feedstock, type of anaerobic digester, and conditions in the digester, such as mesophilic and thermophilic. The biogas production stage consists of a buffer (hygienization) tank and a reactor (anaerobic digester). Previously reported CH_4 emissions from hygienization tanks, anaerobic digesters, and post-digesters are included in this stage (see Table S1).[15–17,19,41,49,50,59,62–76] These emissions are fugitives and venting.

Biomethane production: Biogas upgrading process

The biogas can be upgraded into biomethane by removing impurities. Depending on the biogas quality and the end use, different upgrading technologies can be used. Currently, water scrubbing is the most common commercial technology, followed by chemical scrubbers, membrane, PSA, organic physical scrubber, and cryogenic separation.[77] CH_4 emissions from various upgrading processes, such as carbon filters, chemical and water scrubbers, and membrane technologies, were reported in previous studies[17,19,46,47,49,50,71,78–81] and have been included in the upgrading processes stage (see Table S1). These are fugitives and vent from PSA exhausts and aeration and ventilation ducts.

Transmission, storage, and distribution

Biogas can be utilized to generate heat, electricity, or both. Biomethane can be injected into a gas grid or used as a renewable transport fuel in vehicles. Previous studies reported exhaust CH_4 from cogeneration, electricity production, heat utilization, combined heat and power units, gas engine slip, flare, and gas holder.[17,19,23,41,59,62,67,71,82–85] Emissions from pipeline, flare, compressors, and pressure-relief valves (PRVs) are considered in the transmission, storage, and distribution stage (see Table S1) in order to compare with natural-gas supply chain. End-use emissions mainly coming from incomplete combustion from combined heat and power (CHP), as well as fugitive leaks and vents from energy production units, were not included into emissions from this stage.

Digestate storage

Digestate can be used as is or can be further processed through different methods to be used as fertilizer. The PAS 110 for digestate quality specification is designed to ensure that digestate is no longer classified as waste and is safe and reliable to use as a fertilizer, soil improver, or conditioner, and it recommends that all types of digestate be covered.[45] Although some facilities follow the PAS 110 scheme, none of the published papers address whether the digestate complies with the standard. The solids-liquids separators, such as centrifuge and screw-press separators, membrane filters, biofilters, aerobic treatment, and composting, are widely used to process digestate.[86] The processing and storage of liquid and solid digestate can also cause emissions, depending on the temperature, wind, atmospheric pressure, plant process parameters, and storage tank filling level.[19] Emissions data by digestate types (e.g., solid or liquid) and storage properties (closed or open tanks) were collected from previous studies (see Table S1).[15–17,19,23,24,43,44,49,50,59,62,67,71–73,85,87–92] The emissions are mostly fugitives and venting from open PRVs. The emissions associated with digestate use, such as fertilizer application and post-composting, were excluded from the supply chain because digestate is not always used in the operation area and their emissions are only reported in a few studies.

Miscellaneous emissions

An additional emission stage has been added to account for a variety of sources that are not necessarily present in every biomethane supply chain. The CH_4 emissions from biofilters for odor reduction, compost filters, and separators have been reported in a few studies[19,23,50,51] and are included as miscellaneous emissions.

Whole-site mobile measurements

Whole-site mobile measurements were included for comparisons to the modeled of total emissions from each supply chain.[17,19–23,46,49–51,61–65,71,73,75,88,93] Various emission-measurement techniques were used to quantify emissions and their sources in the whole supply chain, which caused a large variation in emissions.

Supply chain emission models

It is important to determine the probability density function (PDF) of emissions in each stage before running the Monte Carlo simulation.[48] The PDF establishes a good fit of the emissions for each stage, including an uncertainty assessment. Because the emissions in each stage exhibit unique characteristics, particularly with respect to various super-emitters, their data and probability distributions differ (see Table S2 for the characteristics of PDFs). Due to the heavy-tailed distribution (Figure S3) and lack in the sample size, the nonparametric PDF ,which is the KDE, were generated to investigate the PDFs of the emissions from each stage using Python. KDE typically provides more accurate estimates of data distributions than parametric approaches.[94–96] The bandwidth of KDE for each stage was determined automatically in Python's SciPy library using Scott's Rule,[97] which is dependent on the number of data points.[97] The total sample size is 347 and 399 for g $CO_{2\text{-eq.}}/MJ_{HHV}$ and production normalized data, respectively.

Monte Carlo simulation

The total supply chain emissions were estimated using Monte Carlo simulations,[98] which has been widely applied to estimate CH_4 emissions[25,30] with

uncertainty assessment. Each supply chain's PDF, obtained from the KDE, was defined in the simulation to sample from each stage, followed by summing up each stage. Rather than separating the data by feedstock type, we divided it by stage of the supply chain, as shown in Figure S1. The total CH_4 emissions were assessed 10,000 times with random draws from the distributions for each stage. The 10,000 estimates were then used to assess the cumulative CH_4 distribution across the supply chain models by the Python code.

Table 1: SEPA Process

Is SEPA required?	Is the entire proposal defined?	WAC 197-11-060
	Is there an agency "action"?	WAC 197-11-704
	Is the action "categorically exempt"?	WAC 197-11-305 and 800 through 880
	Has SEPA already been completed?	WAC 197-11-164, 600, and 660
Who is lead agency?	Identify the "lead agency."	WAC 197-11-922 through 944
Are there likely to be impacts?	Review the checklist and identify likely significant adverse environmental impacts.	WAC 197-11-330
Are there existing SEPA documents that analyze the impacts?	Identify documents that analyze probable impacts of the proposal.	WAC 197-11-600 and 330(2)(a)
Can impacts be mitigated?	Identify mitigation required by development regulations, and other local and state laws.	WAC 197-11-158, and 330(1)(c)
	Is the applicant willing to change the proposal to reduce impacts?	WAC 197-11-350
	Consider using SEPA substantive authority for other impacts not adequately addressed.	WAC 197-11-660
After application of identified mitigation, is the proposal likely to have any significant adverse environmental impact?	If not, issue a determination of nonsignificance (which may include mitigation measures).	WAC 197-11-340, 350, and 355
	If yes, issue a determination of significance, and either include an adoption notice or begin the EIS process.	WAC 197-11-360 and Part Four
How is SEPA used in decision-making?	Mitigation under SEPA must be included as permit conditions, or in changes to permit applications for the proposal.	WAC 197-11-660
	Projects may be denied if identified significant adverse impacts cannot be mitigated.	

This table is intended as a general overview of the SEPA process, although many details are not included.

1. SEPA—General Background

The State Environmental Policy Act (SEPA) may be the most powerful legal tool for protecting the environment of the state. Among other things, the law requires all state and local governments within the state to:

- "Utilize a systematic, interdisciplinary approach which will insure the integrated use of the natural and social sciences and the environmental design arts in planning and in decision making which may have an impact on man's environment;" and
- Ensure that "...environmental amenities and values will be given appropriate consideration in decision making along with economic and technical considerations...."

The policies and goals in SEPA supplement those in existing authorizations of all branches of government of this state, including state agencies, counties, cities, districts, and public corporations. Any governmental action may be conditioned or denied pursuant to SEPA.

Purpose and Intent

SEPA is intended to ensure that environmental values are considered during decision-making by state and local agencies. When SEPA was adopted, the legislature identified four primary purposes:

(1) “To declare a state policy which will encourage productive and enjoyable harmony between man and his environment;

(2) to promote efforts which will prevent or eliminate damage to the environment and biosphere;

(3) and stimulate the health and welfare of man; and

(4) to enrich the understanding of the ecological systems and natural resources important to the state and nation."

To implement these purposes, the SEPA Rules direct agencies to:

- Consider environmental information (impacts, alternatives, and mitigation) before committing to a particular course of action;
- Identify and evaluate probable impacts, alternatives and mitigation measures, emphasizing important environmental impacts and alternatives (including cumulative, short-term, long-term, direct and indirect impacts);
- Encourage public involvement in decisions;
- Prepare environmental documents that are concise, clear, and to the point;

- Integrate SEPA with existing agency planning and licensing procedures, so that the procedures run concurrently rather than consecutively; and

- Integrate SEPA with agency activities at the earliest possible time to ensure that planning and decisions reflect environmental values, to avoid delays later in the process, and seek to resolve potential problems.

The environmental review process in SEPA is designed to work with other regulations to provide a comprehensive review of a proposal. Most regulations focus on particular aspects of a proposal, while SEPA requires the identification and evaluation of probable impacts for all elements of the environment. Combining the review processes of SEPA and other laws reduces duplication and delay by combining study needs, combining comment periods and public notices, and allowing agencies, applicants, and the public to consider all aspects of a proposal at the same time.

SEPA also gives agencies the authority to condition or deny a proposal based on the agency's adopted SEPA policies and environmental impacts identified in a SEPA document. (See RCW 43.21C.060, WAC 197-11-660, and **Using SEPA in Decision Making**.)

Proposals can be either
project proposals, such as:
- new construction,
- demolition, or
- remodeling

or **nonproject proposals,** such as:
- rulemaking
- comprehensive plans,
- subdivisions, zoning, or
- development regulations.

History

First adopted in 1971, the State Environmental Policy Act (SEPA) provided Washington State's basic environmental charter. Prior to its adoption, the public had voiced concern that government decisions did not reflect environmental considerations. State and local agencies had responded that there was no regulatory framework enabling them to address environmental issues. SEPA, modeled after the National Environmental Policy Act (1969), was created to fill this need. It gives agencies the tools to allow them to both consider and mitigate for environmental impacts of proposals. Provisions were also included to involve the public, tribes, and interested agencies in most review processes prior to a final decision being made.

2. SEPA Environmental Review

The State Environmental Policy Act (SEPA) is intended to provide information to agencies, applicants, and the public to encourage the development of environmentally sound proposals. The environmental review process involves the identification and evaluation of probable environmental impacts, and the development of mitigation measures that will reduce adverse environmental impacts. This environmental information, along with other considerations, is used by agency decision-makers to decide whether to approve a proposal, approve it with conditions, or deny the proposal. SEPA applies to actions made at all levels of government within Washington State. Agency decisions are the hub of SEPA; if there is no agency action,

SEPA is not required.

The SEPA Rules provide the basis for implementing SEPA, and establish uniform requirements for all agencies. By opening up the decision-making process providing an avenue for consideration of environmental consequences, agencies and applicants are able to develop better proposals. Agencies may also deny proposals that are environmentally unsound.

Agency Actions

SEPA environmental review is required for any state or local agency decision that meets the definition of an "action" and is not categorically exempt. Actions are divided into two categories, "project actions" and "nonproject actions".

Project actions are agency decisions to license, fund, or undertake a specific project. For example, project actions include construction or alternation of:

- Public buildings such as city or county offices, jail facilities, public libraries, and school buildings;
- Public facilities such as water and sewer lines, electrical lines, and roads; and
- Private projects such as subdivisions, shopping centers, other commercial buildings, and industrial facilities.

Nonproject actions are agency decisions on policies, plans, and programs, including adoption or amendment of:

- Rules, ordinances, or regulations that will regulate future projects, such as water quality rules, critical area ordinances, and other state and local regulations;
- Comprehensive plans and zoning codes;
- Capital budgets; and
- Road and highway plans;

When deciding if a project requires SEPA review, remember that "agency action" includes not only a license, but also an agency decision to fund or undertake a proposal. Refer to WAC 197-11-704 for a complete definition of an agency action and WAC 197-11-760 for the definition of license.

Summary of the SEPA Process

1. **Provide a preapplication conference (optional).** Although not included in the SEPA Rules, we recommend that agencies offer a process for the applicant to discuss a proposal with staff prior to submitting a permit application or environmental checklist. The applicant and agency can discuss existing regulations that would affect the proposal, the steps and possible timeline for project review, and other information that may help the applicant submit a complete application.

2. **Determine whether SEPA is required**. Determine whether environmental review is required for the proposal by (1) defining the entire proposal, (2) identifying any agency actions (licenses, permits, etc.), and (3) deciding if the proposal fits one of the categorical exemptions. If the project does not involve an agency action, or there is an action but the project is exempt, environmental review is not required.

3. **Determine lead agency**. If environmental review is required, the "lead agency" is identified. This is the agency responsible for the environmental analysis and procedural steps under SEPA.

4. **Evaluate the proposal.** The lead agency must review the environmental checklist and other information available on the proposal and evaluate the proposal's likely environmental impacts. The lead agency and applicant may work together to reduce the probable impacts by either revising the proposal or identifying mitigation measures that will be included as permit conditions.

5. **Distribute draft Checklist for inter-agency and tribal consultation.** Often the best opportunity to make changes to a proposal based on environmental impacts is prior making the threshold determination and issuing the Determination of Nonsignificance or Determination of Significance.

6. **Assess significance and issue a threshold determination**. After evaluating the proposal and identifying mitigation measures, the lead agency must determine whether a proposal would still have any likely significant adverse environmental impacts. The lead agency issues either a determination of nonsignificance (DNS), which may include mitigation conditions, or if the proposal is determined to have a likely significant adverse environmental impact, a determination of significance/scoping notice (DS/Scoping) is issued and the environmental impact statement (EIS) process is begun. The EIS will analyze alternatives and possible mitigation measures to reduce the environmental impacts of the proposal.

7. **Use SEPA in decision-making**. The agency decision-maker must consider the environmental information, along with technical and economic information, when deciding whether to approve a proposal. Decision-makers may use SEPA substantive authority to condition or deny a proposal based on information in the SEPA document and the agency's adopted SEPA policies. (RCW 43.21C.030(b) and 43.21C.060)

Provide a Preapplication Process

Environmental review of a proposal starts long before a lead agency makes a formal determination of whether a project is likely to have a significant impact. Familiarizing the proponent with regulatory requirements and making an informal assessment of likely environmental impacts may lead to changes in the project's location or design that will speed up the formal environmental review and permit approval process. Early environmental project review can reduce expenses and save time for both the proponent and the lead agency.

All agencies are encouraged to offer some form of preapplication process for the applicant. This may be an informal meeting, a site visit, or a formal process with specific requirements. Whatever the format, a preapplication process gives the agency and the applicant an early opportunity to discuss permit application requirements and potential issues. It also provides an opportunity for a "reality check" for the viability of the project and an opportunity to help the applicant understand the review process.

The applicant should provide information on the proposed project, but should not be required to prepare or present detailed plans. Based on the information available, the agency should preliminarily identify applicable regulations and permit needs (including other agency requirements), possible study requirements, potential mitigation, the timeline for review, and other appropriate information.

Issues for agencies to consider when developing a preapplication process include:

- The level of detail needed for a preapplication meeting;
- Whether members of the public should be allowed to participate in the meeting;
- When to invite other agencies to participate;
- Whether to provide a preliminary consistency determination (for GMA jurisdictions);
- Whether and how to provide feedback to the applicant on the results of the meeting;
- How to keep track of the issues discussed and how to access that information when an application is submitted; and
- Methods of making potential applicants aware that the preapplication process is available.

Determine Whether SEPA Is Required

SEPA environmental review is required for all agency actions unless specifically exempted by the SEPA Rules (WAC 197-11-800 to 880) or statute. Agency actions include providing funding or issuing permits for project proposals, and the adoption of plans, regulations, or ordinances for nonproject proposals. (For the full definition of an action under SEPA, see WAC 197-11-704.)

The following steps are used to determine whether SEPA is required:

- Define the total proposal, including any interdependent parts;
- Identify all agency actions required for the proposal (e.g., licenses, funding, etc.); Determine whether the proposal or agency action is categorically exempt.

Some proposals may not require additional environmental review under SEPA if they qualify as a "planned action" under an ordinance adopted by a county or city planning under the Growth Management Act (GMA). In other cases, it may be possible to use existing environmental documents to meet SEPA requirements for a new proposal. (Refer to **Using Existing Documents)**

Defining the entire proposal

- Accurately defining the proposal is key to a successful SEPA process. It is necessary to define the entire proposal to:
- Determine if SEPA is required.
- Determine agencies with jurisdiction and/or expertise.
- Determine lead agency.
- Assure that all related actions are evaluated in a single document, when required (WAC 197-11-060(3)(b)).

Defining the total proposal involves the identification of all the related and interdependent pieces of the proposal. For example, the local agency (city or county) is likely to be lead for development of a dairy farm that consists solely of building construction. If the dairy also required creation of a large water reservoir, the Department of Ecology would become lead agency for the proposal per the lead agency criteria in WAC 197-11-938.

A large proposal involving actions in vastly different locations, such as material being mined at one site, then transported to and processed at another, is another example of defining the entire proposal. Appropriate environmental review would look at the impacts of all the related activities.

It is important to remember that actions are related if they are dependent on each other, so that one will not happen without the other. Related actions may also be spread over time, such as the construction, operation, and closure phases of a proposal.

Related actions may have a single proponent or several. A golf course might be proposed by a private party. However, the city installing a water reuse system needed to serve the site would be a related action. Though the golf course and the water reuse system have separate proponents, since neither would/could proceed without the other, they should be considered together as one proposal under SEPA.

Phased Review

If the proposal consists of a series of actions that are individually exempt, but <u>together</u> may have a significant impact, then the proposal is <u>not</u> exempt. However, the environmental review can be phased or tiered so that SEPA compliance can be done for each phase. Phased review allows agencies and the public to focus on issues that are ready for decision and excludes from consideration issues already decided or not yet ready. (WAC 197-11-060(5)(b))

The sequence of phased review of a project must be from a broad scope to a narrow scope. For example, the review of a multi-phase planned unit development would consist of a general review of the entire proposal and detailed review of those phases ready for construction. Additional review would occur prior to each future phase when adequate information was available to evaluate the environmental impacts.

Phased review is not appropriate when it would merely divide a project to avoid consideration of

cumulative impacts or alternatives. For example, if an industrial facility is proposed, it is not appropriate to limit the review to the impacts of the grade and fill permit without considering construction and operation of the industrial facility.

The "broad to narrow" restriction of phased environmental review does not apply to planning proposals done under the Growth Management Act. For example, the environmental review for the adoption of an interim critical area ordinance (narrow focus) may occur before the review and adoption of the comprehensive plan (broad focus). This is allowed under the 1995 amendments to the SEPA Rules in WAC 197-11-228.

Whenever phased review is used, the SEPA document must clearly state that the proposal is being phased. Future environmental documents should identify the previous documents and should focus on those issues not adequately addressed in the previous documents.

Identify Permits

In defining the proposal, it is necessary to determine what permits or approvals will be needed from state, local, and federal agencies. Some resources that can help are the Office of Regulatory Assistance website includes an Online Permit Assistance System to help you determine which state and federal environmental permits may be needed based on information you provide about a proposal.

When deciding which agency permits or approvals are needed, it may be necessary to consult with other agencies to determine if they have permits or approvals to issue for a specific project. This will help to ensure that all agency actions are identified before determining whether a proposal is categorically exempt.

Categorical Exemptions

There are three separate authorities that contain SEPA exemptions:

1. Statutory exemptions in SEPA listed in RCW 43.21c.
2. SEPA Rule exemptions in WAC 197-11 Part Nine
3. GMA city and county optional provisions
    a. Flexible exemption levels for minor new construction
    b. Eliminate exemptions in critical areas
    c. In-fill exemptions

Some types of projects and some agency actions have been exempted from the requirements of SEPA by the Legislature. These "statutory exemptions" are contained in state law, Chapter 43.21C RCW. The table below summarizes all of the statutory exemptions contained in the SEPA statute as of 2017. Please check the statute for any exemptions adopted after this date. Please remember that this is a summary and the entire exemption must be reviewed before determining if a proposal is exempt from SEPA review.

Statutory Exemption	RCW
Water right for fifty cubic feet of water per second or less for irrigation projects irrigation projects decisions	43.21C.035
Forest practices Class I, II, and III	43.21C.037
School closures	43.21C.038
Air operating permits	43.21C.0381
Watershed restoration projects—Fish habitat enhancement projects	43.21C.0382
Waste discharge permits for existing discharges and certain construction stormwater permits	43.21C.0383
Wireless services facilities (cell towers)	43.21C.0384
Certain actions during state of emergency	43.21C.210
City or town incorporation, consolidation, disincorporation, or annexation of all of a city/town by or of another city/town	43.21C.220 43.21C.222 43.21C.225 43.21C.227
Infill development	43.21C.229
House Finance Commission plans	43.21C.230
Forest Practices Board emergency rules	43.21C.250
Conservation easements, road maintenance & abandonment, Timber harvest schedules involving east-side clear cuts	43.21C.260
Unfinished nuclear power projects	43.21C.400
Battery charging and exchange station installation	43.21C.410
Certain fish protection standards	43.21C.430
Nonproject actions – certain local development regulations	43.21C.450
Categorical exemption for structurally deficient bridges	43.21C.470 43.21C.480

In addition to the statutory exemptions, the Legislature directed rulemaking for types of projects or agency actions that are not subject to SEPA review because the size or type of the activity is unlikely to cause a significant adverse environmental impact. (Refer to SEPA Rules Part Nine.)

Examples of categorically exempt minor projects include construction of four dwelling units or less, commercial buildings with 4,000 square feet or less of gross floor area and no more than

20 parking spaces, and water and sewer facilities related to lines twelve inches or less in diameter. Examples of specific types of agency decisions that are exempt include short plat subdivisions, forest practice class I,II, and III, public property transactions, and business licenses.

Many exemptions for minor new construction or minor land use decisions do not apply when:

- **A rezone is involved;**
- **A license is needed for emissions to air or a discharge to water; or**
- **The proposal involves work wholly or partly on lands covered by water.**

Restrictions are contained in WAC 197-11-305. A proposal that would normally be exempt from SEPA review under Part Nine of the SEPA Rules is not exempt if any of the following apply.

- The proposal is a segment of a proposal that includes a series of related actions, some of which are exempt and some of which are not. For example, the construction of a single family home is usually exempt from SEPA review. However, the single family exemption does not apply when a Class IV forest practice application is required. Since the SEPA statute requires Class IV applications to be evaluated under SEPA, the entire proposal requires SEPA review.
- The proposal includes a series of exempt actions and the lead agency's responsible official determines that together the actions may have a probable significant adverse environmental impact.
- The city or county where the proposal is located has eliminated the categorical exemption for proposals located within a critical area.

To determine if a proposal is exempt from SEPA, review the rule exemptions in Part Nine of the SEPA Rules, the statutory exemptions in SEPA, and any local exemptions and exceptions that may apply. If the proposal meets the criteria for a categorical exemption in either the SEPA Rules or the SEPA statute, no further SEPA review or documentation is required. Remember to watch for "exceptions" and consider the restrictions in WAC 197-11-305.

Categorical Exemptions--Flexible Thresholds

Most categorical exemptions use size criteria to determine if a proposal is exempt. The SEPA Rules allow cities and counties to raise the exemption limit for minor new construction to better accommodate the needs in their jurisdiction. The exemptions may be raised up to the maximum specified in the SEPA Rules (WAC 197-11-800(1)(c). For example, cities and counties may choose to exempt residential developments at any level between 4 and 30 dwelling units in the urban growth area. The exemption for commercial buildings can range between 4,000 and 30,000 square feet. These "flexible thresholds" must be designated through ordinance or resolution by the city or county. If this has not been done, the minimum level applies.

The exemption level set by the county or city will also apply when an agency other than the county or city is lead agency. A state agency or special district may need to consult with the county or city to identify the adopted exemption level for a particular area.

It is also important to remember that the exemptions for minor new construction and minor land use decisions do not apply if any portion of the proposal/decision involves lands covered by water, if a license is needed for a discharge to air or water, or if a rezone is required. (WAC 197-11-800(1)(a) and (2)).

Requirements for Adopting Flexible Thresholds

Several criteria must be met for a city or county to adopt flexible thresholds. Most importantly, the proposal to amend SEPA policies to increase the size of projects exempt from SEPA review must include sufficient documentation that impacts to all elements of the environment have been adequately addressed. There also must be a disclosure of any loss of notice and comment opportunities for future permitting decisions that will be exempt from SEPA.

The documentation that impacts have been adequately address should describe the types, sizes and locations of projects proposed for new exemption level. Impacts to the entire list of SEPA's applicable elements of the environmental must be considered. The proposal should also list the applicable authorities and regulations and describe how much these regulations reduce impacts on each element of the environment for each project types, sizes and locations.

The jurisdiction must also document how specific adopted development regulations and applicable state and federal laws provide adequate protections for cultural and historic resources when exemption levels are raised. A local ordinance or resolution that addresses cultural resources shall include at minimum:

- Use of Available data and other project level review tools, i.e. inventories and predictive models provided by the Department of Archeology and Historic Preservation, other agencies and tribal governments.
- Planning and permitting processes that ensure compliance with applicable cultural resource state laws including chapters 27.44, 27.53, 68.50 and 68.50 RCW.
- Local development regulations that include preproject cultural resource review, where warranted and standard inadvertent discovery (SIDL) for all projects.

Categorical Exemptions in Critical Areas

Cities and counties are required to designate critical areas under the Growth Management Act (GMA). Critical areas are wetlands, aquifer recharge areas, fish and wildlife habitat conservation areas, frequently flooded areas, and geologically hazardous areas. To ensure adequate environmental review of development within these areas, cities and counties may also designate in their SEPA procedures categorical exemptions that do not apply within each critical area. (Refer to WAC 197-11- 908 for the list of exemptions that can be eliminated.)

If a project is not categorically exempt because it is located within a critical area, the environmental review is limited to:

- Documenting whether the proposal is consistent with the requirements of the critical areas

Other agencies should consult with the city or county that has jurisdiction over the project site to determine which categorical exemptions do or do not apply to a proposal.

ordinance;
- Evaluating any significant adverse environmental impacts not adequately addressed by the GMA planning documents and development regulations; and
- Preparing a threshold determination, and an EIS if necessary. (WAC 197-11-908)

Emergency Exemptions

An emergency exemption can be granted by a lead agency when 1) an action is needed to avoid an imminent threat to public health or safety, public or private property, or to prevent serious environmental degradation; and 2) there is not adequate time to complete SEPA procedures. Poor planning by the proponent should not constitute an emergency for the purposes of a SEPA exemption.

Categorical Exemptions for Infill – 2003 Legislation

Cities and counties planning under the Growth Management Act (GMA) must designate urban growth areas, develop comprehensive plans, and adopt implementing regulations to accommodate population growth expected to occur over the next 20 years. As part of this planning effort, GMA cities and counties identify the density of residential development and intensity of mixed use, commercial, and other types of development that will be needed to accommodate the projected population growth.

In 2003, a new section was added to the SEPA statute to encourage infill development at the densities and intensities designated by GMA cities and counties in their comprehensive plans. This new section allows GMA counties and cities to establish categorical exemptions for "…new residential or mixed-use development proposed to fill in an urban growth area designated according to RCW 36.70A.110, where current density and intensity of use in the area is lower than called for in the goals and policies of the applicable comprehensive plan." (RCW 43.21C.229)

Requirements for Adopting Infill Exemptions

Several criteria must be met for a GMA city or county to adopt a categorical exemption for infill:

- The exemption must be limited to new residential or mixed use development within a designated urban growth area;
- The existing density and intensity of use in the urban growth area must be lower than called for in the goals and policies of the applicable city or county comprehensive plan;
- An EIS must have been completed for the adoption of the comprehensive plan; and
- The proposed development must not exceed the density or intensity of use called for in the goals and policies of the applicable city or county comprehensive plan.
- Any infill categorical exemption adopted by a GMA city and county is subject to the same limitations as the categorical exemptions adopted by Ecology in the SEPA Rules.

In addition, many of the categorical exemptions adopted by Ecology do not apply when the proposal is on "lands covered by water". The exemptions for minor new construction in WAC

197-11-800(1) also do not apply if a rezone is required or the project requires a license governing emissions to the air or discharges to water. When establishing a new exemption, the GMA city or county should consider whether one or more of these limitations should be included in the exemption.

GMA cities and counties considering adoption of a new categorical exemption should consider whether the exemption would apply to a project proposed within a critical area. It is recommend that the new exemption not apply in critical areas unless the city or county has updated its critical areas policies and regulations to include best available science under RCW 36.70A.172. This will ensure that the functions and values of critical areas are protected within the urban growth area.

Any categorical exemption adopted under this legislation should be adopted as part of the GMA city or county's SEPA procedures. (Refer to WAC 197-11-904 and 906).

Process for adopting infill categorical exemptions

The following steps are an example of the process that might be used by a GMA city or county to establish a categorical exemption for infill development.

Identify the density and intensity goals specified in the adopted comprehensive plan for residential and mixed use development. If the density/intensity goals have been clearly defined, continue to step 2. If the density/intensity goals are not clearly defined, it may be necessary to update the comprehensive plan before adopting a new categorical exemption.

Evaluate recent residential and/or mixed use projects to identify a specific area(s) where the density/intensity goals in the comprehensive plan are not being met. This review should include consideration of restrictions in other regulations that may prevent the density/intensity from occurring. For example, development in a critical area may be limited due to a wetland buffer zone requirement in the critical area ordinance.

If review of the recent development indicates the density or intensity goals are not being met, identify the development level needed to meet the goals within the selected area.

Evaluate the EIS prepared for the comprehensive plan and determine if the density and intensity goals have been adequately analyzed. Is the analysis up-to-date and does it adequately evaluate the likely environmental impacts of proposed infill development?

If the EIS analysis is not adequate, a supplemental EIS may need to be prepared before adopting an infill exemption. This supplemental EIS should be prepared in conjunction with the adoption or amendment of a subarea plan or an update of the comprehensive plan.

Draft a proposed categorical exemption. The exemption should clearly indicate:

- The level of residential or mixed use development that will be exempt,
- The area where the exemption will apply, and
- How the exemption will be applied to a proposed project.

Review of Proposals

When an application for residential or mixed use development is submitted, the GMA county/city must:

- Compare the proposal to the adopted categorical exemption.
  - Is the proposed density/intensity within the limit established in the exemption?
  - Do any "exceptions" in the categorical exemption apply?
  - Do the criteria in WAC 197-11-305 apply?
  - Is the proposal within a critical area where the exemption does not apply?

If the proposal exceeds the density or intensity in the comprehensive plan, the proposal cannot be exempted.

- Ensure the proposed density or intensity of the development does not exceed the density/intensity levels established in the comprehensive plan. If the proposal meets the criteria in the categorical exemption and does not exceed the density/intensity levels in the comprehensive plan, the proposal is exempt from SEPA review.

Exemption Tips

- The total proposal must be identified before the categorical exemptions can be applied. "Total proposal" means all interdependent parts of a proposal, including all proposed phases. This will limit the piecemeal review of projects, and allow an evaluation of all parts of a proposal. The SEPA Rules do allow phased review under certain circumstances, as defined in WAC 197-11-060(5).

- The SEPA Rules do not require any documentation when a proposal does not meet the definition of an action, or is categorically exempt. However, we recommend the placement of a note in the file or on the permit application (if applicable) to indicate that SEPA compliance had been satisfied or did not apply.

- The Dept. of Ecology considers the exemption for additions or modifications to buildings within WAC 197-11-800(2)(e) to apply to any addition where the existing floor area plus the proposed addition has a total area less than the square footage exempted under WAC 197-11- 800(1) for minor new construction. In other words, SEPA is required for any addition when the <u>total</u> square footage of the entire facility (old plus new) exceeds the threshold adopted by the local jurisdiction. This can include a multi-structure facility.

- If a building is not exempt at the time of construction, neither would any additions to the building be exempt. WAC 197-11-800(3) does exempt minor repair, remodeling (not including additions), and maintenance activities which would not change the use of the building and that does not occur on lands covered by water.

The Lead Agency

For most proposals, one agency is designated as lead agency under SEPA. The lead agency is:

- Responsible for compliance with SEPA procedural requirements.
- Responsible for compiling and assessing information on all the environmental aspects of the proposal for all agencies with jurisdiction.
- The agency responsible for the threshold determination and for the preparation and content of an environmental impact statement when required.

The responsible official represents the lead agency, and is responsible for ensuring adequate environmental analysis is done and the SEPA procedural requirements are met. The responsible official should be identified within the agency's SEPA procedures, and may be a specific person (such as the planning director or mayor), may vary within an agency depending on the proposal, or may be a group of people (such as an environmental review committee or the city council).

Determining Lead Agency

One of the first steps when an application for a new proposal is received is determining who will be the lead agency under SEPA. Usually the agency that receives the first application for a proposal is responsible for determining the lead agency and notifying them of the proposal. If the applicant has filled out an environmental checklist, that is sent to the lead agency with the notification letter.

Lead agency status is determined according to WAC 197-11-922 through 948. If there is a dispute over who shall be lead agency and/or the lead agency cannot be identified, an agency with jurisdiction or the applicant may ask the Department of Ecology for resolution (WAC 197-11-946). Determining the lead agency requires defining the total proposal and identifying all necessary permits. The following criteria are listed in the order of priority:

- If the proposal fits any of the criteria described in WAC 197-11-938, "Lead agencies for specific projects," the agency listed shall be lead.
- If the proponent is a non-federal government agency within Washington State, that agency shall be lead for the proposal.
- For private proposals requiring a license from a city or county, the lead agency is the city or county where the greatest portion of the project is located.
- If a city or county license is not needed, another local agency (for instance a local air authority) that has jurisdiction will be lead.
- If there is no local agency with jurisdiction, one of the state agencies with a license to issue will be lead, based on the priority set in WAC 197-11-936.

Lead Agency Agreements

Any non-federal agency within Washington State may be the lead agency as long as all agencies with jurisdiction agree. The lead agency is not required to have jurisdiction on the proposal.

Two or more agencies may become "co-lead" agencies if both agencies agree. One of the

agencies is named “nominal lead” and is responsible for complying with the procedural requirements of SEPA. All agencies sharing lead agency status are responsible for the completeness and accuracy of the environmental document(s). The written agreement between co-lead agencies, although not required, helps clarify responsibilities, and might typically contain: an outline of each agency’s duties, a statement as to which agency is nominal lead, aspects on how disagreements will be resolved, who will hear appeals, and under what circumstances the contract can be dissolved.

Federal agencies may share lead agency status with a state or local agency to produce a combined NEPA/SEPA document. This allows both agencies to have input into the document preparation, saving time and money, and ensuring that the information needed to evaluate the federal, as well as the state and local permits, is included. This also helps ensure necessary and important coordination among agencies and a more unified understanding of the proposal and mitigation. The co-lead agency agreement can be formalized in a written agreement outlining the responsibilities of both agencies for the environmental review process.

Transfer of Lead Agency Status

A city with a population under 5,000, or a county with less than 18,000 residents may transfer lead agency status for a private proposal to a state agency that has a license to issue for the project. The city or county must forward the environmental checklist and other relevant information on the proposal to the state agency, along with the notification of transfer of lead agency status. The state agency may not refuse. If there is more than one state agency with jurisdiction, the order of priority in WAC 197-11-936 is used to determine which state agency will be the new lead agency.

Assumption of Lead Agency Status

Assumption of lead agency status occurs when the original lead agency issues a determination of nonsignificance (DNS) and another agency with jurisdiction believes that the proposed project is likely to have significant adverse environmental impacts and that an EIS is needed to evaluate the impacts. The notice for lead agency assumption must include a determination of significance.

Any agency with jurisdiction may assume lead agency status during the 14-day comment period on a DNS. If, the lead agency uses the optional DNS process, assumption of lead agency status is made during the comment period on the notice of application. This is the only opportunity for an agency with jurisdiction to assume lead agency status during the optional DNS process. (WAC 197-11-948)

Evaluating the Proposal

Environmental review normally starts with the completion of an environmental checklist. The checklist provides information to the lead agency about the proposal and its probable environmental impacts. It is the lead agency’s responsibility to review the environmental checklist, permit application(s), and any additional information available on a proposal to determine any probable significant adverse environmental impacts and identify potential

mitigation. Consultations with other agencies, tribes, and the public early in the process can help identify both the potential impacts and possible mitigation.

The Environmental Checklist

The environmental checklist is a standard form used by all agencies to obtain information about a proposal. It includes questions about the proposal, its location, possible future activities, and questions about potential impacts of the proposal on each element of the environment (such as earth, water, land use, etc.). The environmental checklist form is located on the SEPA Templates webpage. Guidance on completing and reviewing the environmental checklist is available on the Checklist Guidance webpage and help links are included in the downloaded Checklist template.

The lead agency may choose to fill out the checklist or may require the applicant to fill it out. An advantage to the applicant completing the checklist is that it causes them to examine their proposal from an environmental perspective and they may be motivated to make improvements. If the applicant completes the checklist, the lead agency must review the answers and make corrections and/or additions, if appropriate. For example the lead agency should verify:

- Is the project description complete?
- Have all interdependent pieces of the project been identified? (Refer to WAC 197-11-060(3))
- Have all necessary permits and licenses from local, state, and federal agencies been identified?
- Is the location adequately identified?
- Are the descriptions of the environment complete and accurate?

A thorough review and written revisions to the checklist by the lead agency is critically important because the checklist (and other reports if available) supports the legal validity of the threshold determination. It is also:

- Important for receiving useful feedback from other agencies, tribes, and the public;
- necessary for providing other agencies with jurisdiction with environmental information prior to making decisions on the proposal, and;
- part of the environmental record for an agency decision.

The checklist was designed to be as generic as possible to ensure that it was applicable to every kind of proposal. The items in the checklist are not weighted. The mention of one or more adverse impacts does not necessarily mean they are significant. (WAC 197-11-315(5)) In most cases, if the questions are answered accurately and completely, the impacts of a proposal can be ascertained. If necessary, the lead agency may request additional information from the applicant after conducting the initial review of the checklist. (WAC 197-11-100, 315, 335)

Consultations

Consultations may involve meeting with other agencies, or circulating the checklist and other environmental documents for comment prior to a threshold determination. This can assist the

lead agency in determining permits needed, appropriate mitigation to require, any additional information and/or studies needed, and when an environmental impact statement is or is not needed for a proposal. WAC 197-11-920 includes a list of agencies with expertise on elements of the environment.

Consultations are intended to gather information from agencies with expertise. There is no set form that a consultation must take. It is important that it contain sufficient information for agencies to provide valuable comments, including a clear description of the proposal. At a minimum, the environmental checklist should be included with a written consultation request. Information should also be included on when the comments must be returned for consideration by the lead agency, as well as an agency contact, address, and phone number.

Identify Mitigation

Mitigation is the avoidance, minimization, rectification, compensation, reduction, or elimination of adverse impacts to built and natural elements of the environment. Mitigation may also involve monitoring and a contingency plan for correcting problems if they occur.

When considering the need for mitigation measures, the lead agency should review the environmental checklist and other information available on the proposal, including consultations with other agencies. Mitigation required under existing local, state, and federal rules may not be sufficient to avoid, minimize or compensate for significant impacts. It is important to identify applicable regulations and then analyze and disclose the extent to which they reduce the specific impacts of the specific proposal under SEPA review.

Additional mitigation can be applied to a proposal with the use of SEPA substantive authority, based on identified potential adverse impacts related to the proposal and the agency's adopted SEPA procedures. (See section on Using SEPA in Decision Making) Mitigation conditions must also be reasonable and capable of being accomplished.

It may also be possible to work cooperatively with the proponent to make changes to the proposal that will reduce and eliminate the significant adverse impacts. Voluntary mitigation may sometimes exceed the level that may be required of the applicant under regulatory authority, and produce a much improved and more desirable project. Mitigation conditions must be included in the permit, license or other approval to be binding.

Other agencies with jurisdiction or expertise, and the public may assist the lead agency in determining appropriate mitigation for a proposal. This can be done prior to the threshold determination (see discussion on Notices of Application and Consultations), or may result from comments received on a threshold determination (DNS or DS/scoping notice), or draft EIS.

Assess Significance

The SEPA "threshold determination" is the formal decision as to whether the proposal is likely to cause a significant adverse environmental impact for which mitigation cannot be easily identified. The SEPA Rules state that significant "means a reasonable likelihood of more than a

moderate adverse impact on environmental quality". It is often non-quantifiable. It involves the physical setting, and both the magnitude and duration of the impact. SEPA Rules state that the beneficial aspects of a proposal shall not be used to balance adverse impacts in determining significance.

In evaluating a proposal, the lead agency reviews the environmental checklist and other information about the proposal, and should consider any comments received from the public or other agencies (through consultations, a notice of application, prethreshold meetings, etc.). Likely adverse environmental impacts are identified and potential mitigation is taken into account—particularly that already required under development and permit regulations. The responsible official must then decide whether there are any likely significant adverse environmental impacts that have not been adequately addressed.

The severity of the impact must be weighed as well as its likelihood of occurring. An impact may be significant if its magnitude would be severe, even if its likelihood is not great. In determining if a proposal will have a significant impact, the responsible official may consider that a number of marginal impacts may together result in a significant impact. Even one significant impact is sufficient to require an environmental impact statement.

If significant impacts are likely, a determination of significance (DS) is issued and the environmental impact statement process is started. If there are no likely significant adverse environmental impacts, a determination of nonsignificance (DNS) is issued. Additional guidance for making the threshold determination is included in WAC 197-11-330.

Considerations During the Threshold Determination Process

When evaluating the proposal, the responsible official must consider a number of issues. The following are examples of the type of questions that need to be answered during the review process.

- Are the permit application(s) and environmental checklist accurate and complete?
- Are there any additional studies and/or information available that would help in the evaluation of the proposal? (i.e. an environmental impact statement on the comprehensive plan, or on a similar project, or on a project at a similar location.)
- Are specific studies needed under the (1) development regulations, (2) SEPA, or (3) other local, state, or federal regulations that must be made available prior to making the threshold determination? For example, is a wetland study, a transportation study, or an archaeological review needed?
- Is early consultation with tribes, other agencies, and/or the public required or would it be beneficial? What form should this take?
- Is the project consistent with the local critical area ordinances, development regulations, and comprehensive plans?
- Is the proposal consistent with other local, state, and federal regulations (such as those governed by regional air authorities, health districts, and state natural resource agencies)?
- Will mitigation/conditions be required by the local development regulations

or other local, state, or federal regulations?

- What are the likely adverse environmental impacts of the proposal? Have the reasonable concerns of tribes, other agencies, and the public been met?
- Is the applicant willing to change the proposal to eliminate or reduce the likely adverse environmental impacts of the proposal?
- Are there additional environmental impacts that have not been mitigated? Are there possible mitigation measures that could be required using SEPA substantive authority to mitigate those impacts?
- Are there likely significant adverse environmental impacts that have not been mitigated to a nonsignificant level?

Revising and adopting existing documents

For agency decisions (actions) on the same proposal, existing SEPA documents can be revised and supplemented to provide new information. Instead of preparing a new environmental checklist or Environmental Impact Statement (EIS), agencies can adopt and use previous reviews that include a relevant analysis of all or part of a new proposal.

Revising SEPA documents for the same proposal

The lead agency is responsible for completing the environmental review process for all agencies with jurisdiction. This means other agencies with jurisdiction do not prepare separate SEPA documents or adopt the environmental documents issued by the lead agency for the same proposal.

However, SEPA documents do not have arbitrary expiration dates and can be modified — including revised Determinations of Nonsignificance (DNS), EIS Addendums, or Supplemental EIS — to better inform a pending agency decision. Modifying, revising, and supplementing exiting SEPA documents can be done for the same proposal.

If a DNS or mitigated determination of nonsignificance (MDNS) was previously issued and new information warrants additional analysis, the lead agency can withdraw or modify the DNS and issue a Revised DNS with additional supporting information such as a new staff report, or a new or revised checklist or addendum.

A draft EIS can be modified using an addendum or changes can be reflected in a revised draft EIS. A final EIS can be modified by issuing an addendum or supplemental EIS.

If a proposal is delayed so new permits must be applied for after SEPA review is done, then the additional review process could be limited to:

- Verifying that there is no new environmental information.
- Determining regulatory changes or changes to the proposal require additional SEPA review.

Any notice and comment provided for the underlying permit should still include previous SEPA documents to ensure the permitting agency considers any new or additional information.

Adopting previous SEPA reviews for new proposals

If the impacts associated with a new proposal have been adequately evaluated in a previously-issued SEPA or NEPA document, the document can be adopted to satisfy SEPA requirements. While a lead agency may adopt all or part of the information and environmental analysis in the adopted documents, they will need to make a new threshold determination.

Using existing documents is particularly important cities and counties planning development under the state **Growth Management Act (GMA)**. Jurisdictions that have completed an environmental analysis for their comprehensive plans and development regulations can use the analysis as starting point for reviewing individual projects, allowing them to focus just on those aspects that have yet to be addressed. GMA cities and counties can also use the new Planned Action process in which formal SEPA review is done before proponents submit permit applications for projects.

Agencies can only use documents from a previous SEPA or NEPA review. This is why it is critical to provide a thorough description of the current proposal and clearly identify the SEPA documents being adopted.

In addition, agencies adopting existing environmental documents must independently determine if they meet environmental review standards and a proposal's needs. To be adopted, previous SEPA documents are not required to meet an agency's own preparation procedures. However, in all cases, agencies are required to issue new threshold determinations. They can use the following previous SEPA documents:

- **Adoption / determination of significance (DS)** is issued when an existing EIS addresses all probable significant adverse environmental impacts and reasonable proposal alternatives. While a new comment period is not required, a agency must distribute the adoption notice. There is a 7-day waiting / reading period before an agency can take an action.
- **Adoption / DS and addendum** follows the same procedure as the adoption / DS, except an addendum adding minor new information is circulated with the adoption notice.
- **Adoption / DS and Supplemental EIS** is used when an existing EIS addresses some, but not all, of a new proposal's probable significant adverse environmental impacts. The EIS can be used as the basis for a new supplemental EIS and the adoption notice must be included in the draft and final supplemental EIS.
- **Adoption / Determination of Nonsignificance** is used for existing DNS and environmental checklist, NEPA environmental assessment, or documented categorical exclusion is adopted for a new proposal using the combined adoption / DNS template. The agency must follow DNS procedures including a comment period, distribution, and public notice.

When adopting a document, a copy must be available for review — although the lead agency is not required to recirculate copies with the adoption notice, except to agencies with jurisdiction that have not already received them. Agencies are encouraged to distribute copies of adopted or incorporated SEPA documents to agencies with expertise or interest in the proposal, as well as affected tribal governments. Include the SEPA determination whenever possible since

these documents assist in adequately evaluating a proposal.

Incorporation by reference

Incorporation by reference is similar to directly adopting a previous SEPA document. This is because all or part of the incorporated document becomes part of the agency environmental documentation for a proposal. Unlike the adoption process which is limited to environmental documents issued under either SEPA or NEPA, any information may be incorporated by reference such as studies or reports that provide information relevant to a proposal. To incorporate documents by reference, the agency must identify and describe the documents in the current environmental checklist, threshold determination, or EIS.

Issuing a Determination of Nonsignificance

A determination of nonsignificance (DNS) is issued when the responsible official has determined that the proposal is unlikely to have significant adverse environmental impacts, or that mitigation has been identified that will reduce impacts to a nonsignificant level. (For help making the threshold determination, refer to section on how to Assess Significance**)** The DNS may or may not require a public comment period and circulation to other agencies.

If the lead agency is a GMA city or county, there are specific restrictions under the Local Project Review Act on when a DNS can be issued during the "integrated review process." To avoid needless delays sometimes caused by these restrictions, the "Optional DNS Process" was added to the SEPA Rules.

Mitigated DNS

A primary goal of SEPA is to reduce or eliminate environmental impacts. If significant impacts are identified that would require the preparation of an EIS, those impacts can be reduced either by the applicant(s) making changes to the proposal or by requiring mitigation measures as a condition of approving the project. When changes to the proposal or mitigation measures are identified that will reduce the identified significant adverse impacts down to a nonsignificant level, a "mitigated DNS" is issued in lieu of a Determination of Significance and preparation of an EIS. The mitigating measures are typically shown on the face of the DNS, or as an attachment. A 14- day comment period, distribution, and public notice are always required for mitigated DNS.

SEPA substantive authority can also reduce or eliminate adverse environmental impacts that may be less than "significant". (See section 6 for more information on Using SEPA in Decision Making.)

DNS Comment Period

With the exception of projects for which the optional DNS process is used, if <u>any</u> of the following criteria applies to the proposal, a 14-day comment period is required for the DNS prior to agency action.

- There is another agency with jurisdiction (license, permit, or other approval to

issue).

- The proposal includes demolition of a structure not exempt under WAC 197- 11-800(2)(f) or 197-11-880.
- The proposal requires a non-exempt clearing and grading permit.
- The proposal is changed or mitigation measures have been added under WAC 197-11-350 that reduce significant impacts to a nonsignificant level (mitigated DNS).
- The DNS follows the withdrawal of a determination of significance (DS) for the proposal. (This applies even if the DNS and the withdrawal are issued together.)
- The proposal is a GMA action.

Public Notice and Circulation of a DNS

If a comment period is required for a DNS, public notice and circulation requirements must be met. This ensures agencies with jurisdiction, affected tribes, and concerned citizens know about the proposal and have an opportunity to participate in the environmental analysis and review.

The DNS and the checklist must be sent to:

- The Department of Ecology;
- All agencies with jurisdiction (state, local and federal);
- Affected tribes; and
- All local agencies or political subdivisions whose public services would be affected by the proposal.

Public notice procedures should be stipulated within the lead agency's adopted SEPA procedures. A list of reasonable methods to provide public notice is included in WAC 197-11-510(b). Those agencies that have no stipulated SEPA public notice procedures are required at a minimum to:

- Post the property, for site-specific proposals; and
- Publish notice in a newspaper of general circulation in the area where the proposal is located.

Additional public notice efforts are not required, but are encouraged for important or controversial proposals—regardless of environmental significance. Public hearings or meetings can provide additional avenues for public involvement, comment, and discussion. Many agencies have developed innovative means to "get the word out" to affected community members that may not be reached by more traditional methods. Examples include distributing bilingual flyers or advertising on non-English radio stations.

TIP: Whenever possible, the lead agency should combine the public notice for the DNS comment period with the public notice for any comment period and/or public hearing held on the permit or license.

Table 2: SEPA Document Distribution/Notification Requirements

Document	Comment Period	Public Notification	Agency Distribution *(jurisdiction, expertise, services affected, Tribes) Send electronic or paper copy*	SEPA Register Submittal separegister@ecy.wa.gov *send electronic copy (except one hardcopy of EISs)*
Determination of Nonsignificance (DNS) WAC 197-11-340(2)	Minimum 14 days -if required per WAC 197-11-340(2)	If comment period required, Per agency procedures or SEPA rules	Required to distribute If comment period DNS letter **plus checklist** Staff report if available	Required for all DNSs **Require electronic documents** DNS letter **plus checklist** Staff report if available
Mitigated DNS WAC 197-11-340 and 350	Minimum 14 days	Required	Same as above	**Require electronic documents** DNS letter **plus checklist** Staff report if available
Optional DNS process WAC 197-11-355 **DNS- NOA** **DNS issued after NOA**	Combined with NOA (14 to 30 days) Optional 14 days	Required Optional (but required if there's a comment period)	Required to distribute Include checklist Required – but not the Checklist unless it's been revised	Required to submit **Require electronic documents** Clearly stating *NOA and Optional Process* **Include checklist** **Require electronic documents** but no checklist unless it's been revised
Revised/Modified DNS or MDNS WAC 197-11-340(2)(f)	Not required but recommended – especially if it's an MDNS	Not required but recommended – especially if it's an MDNS	Required – but not the Checklist unless it's been revised	**Require electronic documents** No checklist unless revised

DNS after withdrawal of a DS or previous DNS WAC 197-11-360(4) and 340(2)(iv)	Minimum 14 days	Required	Required to distribute -Include checklist	Required to submit **Require electronic documents** Include checklist
Determination of significance (DS) with Scoping notice WAC 197-11-360, 408, and 410	21 days, up to 30 days for "expanded scoping"	Required	Required to distribute	Required to submit **Require electronic documents**
Draft environmental impact statement (EIS) WAC 197-11-455	30 days, with possible 15-day extension	Required Public Hearing required upon request	Required to submit Distribute DEIS (hardcopy or electronic)	Required to submit **One hardcopy plus one CD**
Supplemental draft EIS WAC 197-11-620(1) and 455	Minimum 30 days	Same as above	Same as above	Same as above
Final EIS WAC 197-11-460	No, but a 7-day waiting period is required before agency action	Not required, but notification to interested parties/parties of record	Same as above	Same as above
Final supplemental EIS WAC 197-11-620(1) and 460	No, but 7-day wait	Same as above	Same as above	Same as above
Adoption Notice with DNS WAC 197-11-340(2) and 630	Minimum 14 day comment period. (unless it's not required under WAC 197-11-340.	Yes, if comment period required	Required Distribute document adopted or provide website access	Required to submit **Require electronic documents** Include document adopted or provide website access
DS/Adoption of EIS (no Supplemental or Addendum) WAC 197-11-630(3)	Not required but 7-day wait	Not required, but encouraged, to notify parties of interest	Same as above	Same as above
Addendum to an EIS WAC 197-11-625	Not required unless comment period on underlying action	Distribute to recipients of EIS	Required Distribute addendum plus CD or access to original EIS	Required to submit **One hardcopy and one CD** of addendum and CD or website access to original EIS

Note: Agencies may automatically extend any comment period for public proposals WAC 197-11 050(7).

Responding to Comments on a DNS

The SEPA Rules require the responsible official to consider all timely comments made on a DNS. The lead agency may then choose to retain the DNS, issue a revised DNS, or—if significant adverse impacts have been identified—they may withdraw the DNS and issue a determination of significance (DS).

Retaining the DNS: If the lead agency decides to retain the DNS, agencies may take action on the proposal after the close of the comment period. A decision to retain a DNS requires no additional paperwork, although some agencies choose to circulate notice to agencies with jurisdiction and other interested parties. Other agencies place a memo in the file indicating the comments have been reviewed and no further review is needed. Sending a written response to commenters or arranging a meeting is at the discretion of the lead agency, but can be beneficial— both in establishing good public rapport and in developing an improved proposal.

Revising the DNS: A revised DNS is most often issued when there is a change in the mitigation conditions that will be applied to a proposal. It may also be used to document changes to a proposal that will not result in any likely significant adverse environmental impacts. A modified or revised DNS must be circulated to agencies with jurisdiction[46], but does not require an additional comment period.

Public notice and a comment period is generally not required unless there is an additional comment period on the underlying action (permit or plan). The format of a revised DNS is similar to other DNSs so the lead agency should clearly indicate that it is a revised or modified DNS and identify the document being modified (project description, date of issue, etc.). Recirculation of an un-changed checklist is not required, but is required when notable changes have been made or enough time has passed that the original may no longer be available.

Withdrawing the DNS: The lead agency must withdraw the DNS if:

- There are substantial changes to the proposal that are likely to result in significant environmental impacts;
- There is new information available on a proposal's probable significant adverse environmental impacts; or
- The DNS was obtained by misrepresentation or lack of material disclosure on the part of the proponent.

It is also advisable to withdraw a DNS if the lead agency determines that it needs time to reconsider the significance of the proposal, reassess mitigation needs, or to do additional investigation. A new threshold determination and comment period will be required, but this will prevent the "locking in" of the original DNS by another agency issuing a non-exempt permit. Locking-in of the DNS can restrict the lead agency's ability to impose additional mitigation measures for impacts not identified in the original DNS, or to require that an EIS be prepared.

The notice of withdrawal must be circulated to all agencies with jurisdiction. There is no set format for a withdrawal notice, but agencies should clearly identify the document being withdrawn, the project description and location, and the applicant's name. It also may be helpful to include information on the reason for the withdrawal.

3. Environmental Impact Statement Process

An environmental impact statement (EIS) is prepared when the lead agency has determined a proposal is likely to result in significant adverse environmental impacts (see section on how to **Assess Significance**). The EIS process is a tool for identifying and analyzing probable adverse environmental impacts, reasonable alternatives, and possible mitigation.

The EIS process:

- **Provides opportunities for the public, agencies, and tribes to participate in developing and analyzing information**. Public, agency, and tribal input help to identify a proposal's significant adverse environmental impacts, reasonable alternatives, possible mitigation measures, and methods of analysis for the EIS. Outside participation during all phases of the process increases understanding of the proposal and garners trust.

- **Improves proposals from an environmental perspective.** Proposals are improved through mitigation of identified adverse environmental impacts, and development of reasonable alternatives that meet the objective of the proposal. Changes may be made voluntarily by the proponent, or they may be mitigated through SEPA substantive authority or other regulatory authority. Through the EIS process, areas of controversy and other significant issues are identified early when the opportunities to consider a broad range of solutions are greatest.

- **Provides decision-makers with environmental information.** An EIS provides decision-makers and the public with a complete and impartial discussion of the proposed project, existing site conditions, probable significant adverse environmental impacts, and reasonable alternatives and mitigation measures that would avoid or minimize adverse impacts. This provides the information needed for informed decisions.

- **Provides the information necessary for conditioning or denying the proposal.** Based on information in the EIS and the agency's adopted SEPA policies, SEPA substantive authority allows a decision-maker to:
    - Deny a proposal when "significant" environmental impacts cannot be reasonably mitigated;
    - Place additional conditions on the project to protect the environment from adverse environmental impacts; or
    - Approve the proposal without further mitigation.
    (See section on **Using SEPA in Decision Making**)

There are several steps in the EIS process:

1. Conducting "scoping," which initiates participation by the public, tribes, and other agencies and provides an opportunity to comment on the proposal's alternatives, impacts, and potential mitigation measures to be analyzed in the EIS;
2. Preparing the draft EIS, which analyzes the probable impacts of a proposal and reasonable alternatives, and may include studies, modeling, etc.;
3. Issuing the draft EIS for review and comment by the public, other agencies, and the tribes;
4. Preparing the final EIS, which includes analyzing and responding to all comments received on the draft EIS, and may include additional studies and modeling to evaluate probable impacts not adequately analyzed in the draft EIS;
5. Issuing the final EIS; and
6. Using the EIS information in decision-making.

There are two types of EISs: project and nonproject (often referred to as programmatic).

A **project EIS** is prepared for a proposal that generally involves physical changes to one or more elements of the environment (see WAC 197-11-444 for a list of the elements of the environment). Examples of the types of proposals that could be analyzed in a project EIS include:

- New construction,
- Facility operation changes,
- Demolitions
- Environmental clean-up projects, and
- The purchase, sale, lease, transfer, or exchange of natural resources (such as the lease of public lands for timber harvest).

A **nonproject EIS** is prepared for planning decisions that provide the basis for later project review. Nonproject actions are the adoption of plans, policies, programs, or regulations that contain standards controlling the use of the environment or that will regulate a series of connected actions. Examples include comprehensive plans, watershed management plans, shoreline master programs, and development regulations. (See **Nonproject Review** section)

Encouraging Public Participation in the EIS

Including the public early in the EIS process is key to identifying public issues, establishing communication lines, and facilitating trust. Taking time up-front to plan how to involve the public and being responsive to the public's needs as the process proceeds can result in a more complete and accurate document and a more satisfied public. Early involvement can also avoid later pitfalls and unnecessary delays.

SEPA requires agencies to involve the public during:

1. The "scoping" period, where agencies, tribes, and the public are invited to comment on the range of alternatives, areas of impact, and possible mitigation measures that should be evaluated within the EIS; and

2. The draft EIS review period, where comments are requested on the merits of the alternatives and the adequacy of the environmental analysis.

Agencies are encouraged to think beyond regulatory requirements in determining how best to inspire public participation and create interagency cooperation. Agencies may enhance the required involvement opportunities or add to them, as the proposal warrants. For example, under "expanded scoping," SEPA suggests several methods for enhancing public involvement beyond the basic requirements. The intent is to provide agencies with maximum flexibility to meet the purposes of scoping. Additionally, the lead agency may elect to provide supplementary opportunities for communicating with the public, starting before the determination of significance/scoping notice is issued and continuing throughout the EIS process.

A public participation plan can be a valuable tool in the EIS process. The lead agency should begin planning for public participation prior to issuing the scoping notice, as this initiates the formal involvement of agencies, tribes, and the public. Agencies may also find that pre-threshold meetings can be useful, even when it is certain that an EIS will be required. In developing the plan, the agency should consider each of the different stages of the process and then identify which methods would work best for the stage in question. The agency may also wish to consider extending the participation plan through the permitting stage as well.

Scoping

Scoping is the first step in the EIS process. The purpose of scoping is to narrow the focus of the EIS to significant environmental issues, to eliminate insignificant impacts from detailed study, and to identify alternatives to be analyzed in the EIS. Scoping also provides notice to the public and other agencies that an EIS is being prepared, and initiates their involvement in the process.

The scoping process not only alerts the lead agency, but also the applicant to areas of concern and controversy early in the process. As a result, it offers more opportunities for the applicant to consider and explore means to address the concerns. From an environmental perspective, this can result in changed proposals with fewer environmental impacts.

Issuing a Determination of Significance/Scoping Notice

Once the responsible official determines an EIS is needed, a determination of significance/scoping notice (DS/Scoping) is issued. The form is located in the SEPA Rules at WAC 197-11-980. This form may be modified by the lead agency, but informational fields (i.e. project description, applicant, etc.) should not be omitted. The scoping notice should give as thorough a description of the proposal as possible and should include information on the areas to be addressed in the draft EIS. If the lead agency has identified possible alternatives, they should also be described in the scoping notice.

The scoping process begins when the lead agency circulates the DS/scoping notice and gives

public notice. The date of issuance is the date the scoping notice is sent to the Department of Ecology, agencies with jurisdiction, and is made available to the public. Agencies and the public are encouraged to provide comments on the proposal and scope of the EIS, including commenting on alternatives, mitigation measures, and probable significant adverse impacts.

The lead agency may use various methods to involve the public in the scoping process:

- **Written comment periods.** The lead agency must give public notice and circulate the scoping notice for public and agency comment[52]. If a GMA county or city issues a scoping notice in combination with a notice of application, the comment period for the NOA is used (between 14 and 30 days, as determined by the lead agency). For non-GMA agencies, the comment period is 21 days, unless expanded scoping is used to extend the comment period to as many as 30 days.

- **Expanded scoping.** The use of expanded scoping is intended to enhance public and agency participation in identifying the scope of an EIS. Expanded scoping typically runs 30 days, rather than the standard 21-day written comment period. The additional time enables the lead agency to expand the methods used for informing agencies, tribes, and public of the proposal and to gain their input. It can involve the use of public or interagency meetings, the circulation of questionnaires or information packets, the coordination and integration of other government reviews, etc. (Refer to WAC 197-11-410 for other suggested methods of doing expanding scoping.)

Responding to Scoping Comments

Although no formal response to the scoping comments is required, some agencies choose to prepare a scoping document that 1) summarizes the comments received during the scoping process; 2) identifies the elements of the environment, alternatives and mitigation measures to be analyzed; and 3) provides other relevant information.

The scoping document can be a valuable tool to:

- Provide a record of the scoping process;
- Provide a summary of the issues raised during scoping;
- Communicate the decisions made on what is to be analyzed in the EIS; and
- Provide a reference for the reader to assess whether the agency has heard all the concerns and is accurately interpreting them.

Determining the Scope of the EIS

After reviewing the comments received during scoping, the lead agency must determine the scope of the EIS. The lead agency selects the alternatives and the elements of the built and natural environment[54] that will be analyzed in the EIS. The alternatives selected must include the proposal, the no-action alternative, and other reasonable alternatives. The elements of the environment that are evaluated in the EIS should be narrowed to just those that may be significantly impacted.
For example, an EIS for an apartment complex in a large city might focus only on transportation issues. Minimizing discussion of nonsignificant issues makes the document

more readable for reviewers and useful to decision-makers. (Additional guidance on defining the no-action alternative and identifying reasonable alternatives can be found in Section 3)

Revising the Scope of the EIS

The scope of the EIS can be revised by the lead agency whenever changes to the proposal are made, or new information is learned. This does not always require a new DS/Scoping notice. The lead agency should consider whether the intent and purpose of preparing the EIS would be compromised –if scoping is not reissued or improved –if scoping is redone.

Withdrawing a DS/Scoping Notice

A determination of significance (DS) is withdrawn by the lead agency if:

- the applicant withdraws the proposal (no new threshold determination), or
- the proposal has been changed so there will no longer be any significant adverse impacts (DNS or MDNS required).

There is no set format for the notice of withdrawal; it may take the form of a memo or letter, or it may be combined with a new threshold determination. The notice of withdrawal should be circulated to the Department of Ecology and any agencies with jurisdiction. When a DNS is issued for a proposal for which a DS has been withdrawn, a 14- day public comment period, public notice, and distribution of the DNS and checklist are required. In addition to the Department of Ecology, agencies with jurisdiction, and affected tribes, a copy of the DNS must be sent to anyone who had commented on the DS/scoping notice.

Purpose and Content of an EIS

The primary purpose of an EIS is to provide an impartial discussion of significant environmental impacts, and reasonable alternatives and mitigation measures that avoid or minimize adverse environmental impacts. This environmental information is used by agency officials—in conjunction with applicable regulations and other relevant information—to make decisions to approve, condition, or deny the proposal. (See Using SEPA in Decision Making)

An EIS is not meant to be a huge, unwieldy document. The text of a typical EIS is intended to be only 30 to 50 pages. It is not to exceed 75 pages unless the proposal is of unusual scope or complexity, in which case it may not exceed 150 pages. The EIS should provide information that is readable and useful for the agencies, the applicant, and interested citizens.

A readable document:

- Is well organized;
- Provides useful tools for the reader, such as a table of contents, glossary, index, references;
- Is not overly technical (technical details necessary to support information and conclusions in the EIS should be included in appendices or incorporated by reference); and

- Is brief and concise.

A useful document:

- Focuses on the most significant and vital information concerning the proposal, alternatives, and impacts;
- Provides sufficient information about each alternative so that impacts can be compared between alternatives; and
- Presents the lead agency's analysis and conclusions about the likely environmental impact of the proposal.

Format requirements for an EIS are outlined in WAC 197-11-430, 440, 442, and 443. A cover letter or memo is required and the fact sheet must be the first section of every EIS. (A sample fact sheet can be found in Appendix D, on page 140.) Otherwise, the lead agency has the flexibility to use any format they think appropriate to provide a clear understanding of the proposal and the alternatives.

The lead agency is responsible for the content of the EIS and for meeting the procedural requirements of the SEPA Rules. The lead agency, the applicant, or an outside consultant can prepare the EIS[59]. The lead agency must specify, within its own SEPA procedures, the circumstances and limitations under which the applicant will participate in the preparation of the EIS.

Describing the Proposal

Explaining what is being proposed is fundamental to the usefulness of the EIS. Therefore, the EIS should:

1. Describe the <u>total proposal</u>:
   - For project actions, this includes construction activities, operation/use, and post operation/closure.
   - For nonproject actions, this includes adoption and implementation of a plan, policy or rule.
2. Describe any related physical activities and physical changes/disturbances. For example, the construction of an electrical line or water line extension needed to service the project, or the development of a borrow pit to provide fill for the project site, etc.

3. Include information on any agency requirements that would be applied to the proposal that relate to the elements of the environment. For example, mitigation required under a critical area ordinance, or requirements from a storm water rule, etc.

Agencies are encouraged to describe a proposal as an objective, particularly for agency actions. For example, a city could propose the construction of a series of settling ponds and a chlorination system at the wastewater treatment facility. Instead, the proposal could be described as meeting the wastewater treatment needs of future development for the next 15 years. This encourages the consideration of a wider range of alternatives, where different treatment processes, and even water reuse options are contemplated rather than limiting the consideration to size and location options.

Identifying Alternatives

The EIS evaluates the proposal, the no-action alternative, and other "reasonable alternatives"[60]. A reasonable alternative is a feasible alternate course of action that meets the proposal's objective at a lower environmental cost. Reasonable alternatives may be limited to those that an agency with jurisdiction has authority to control either directly or indirectly through the requirement of mitigation.

Alternatives are one of the basic building blocks of an EIS. They present options in a meaningful way for decision-makers. The EIS examines all areas of probable significant adverse environmental impact associated with the various alternatives including the no-action alternative and the proposal.

Project alternatives might include design alternatives, location options on the site, different operational procedures, various methods of reclamation for ground disturbance, closure options, etc. For public projects, alternative project sites should also be evaluated. For private projects, consideration of off-site alternatives may be limited prohibited except under certain circumstances (see WAC 197-11-440(5)(d)).

It is not necessary to evaluate every alternative iteration. Selecting alternatives that represent the range of options provides an effective method to evaluate and compare the merits of different choices. The final action chosen by decision- makers need not be identical to any single alternative in the EIS, but must be within the range of alternatives discussed. (Additional analysis in a supplemental EIS or in an addendum can be used to address any portions of the final proposal that lie outside the analysis in the EIS. See section on Use of Existing Documents**)**

As potential alternatives are identified, they should be measured against certain criteria:

- Do they feasibly attain or approximate the proposal’s objectives?
- Do they provide a lower environmental cost or decreased level of environmental degradation than the proposal?

It may not be evident at the beginning of the process whether an alternative meets all of these criteria. The lead agency should continue to analyze each alternative until information becomes available that indicates an alternative fails to meet the criteria. The alternative can then be eliminated from further consideration. Any decisions to eliminate an alternative and the reasons why should be documented in the EIS.

Occasionally, a lead agency may decide that there are no reasonable alternatives to a proposal. In this case, the no- action alternative and the proposed action would be the only alternatives examined in the EIS.

As part of the discussion of alternatives, the EIS must discuss the benefits and disadvantages of delaying implementation of the proposal. The urgency of implementing the proposal can be compared to any benefits of delay. The foreclosure of other options should also be considered (i.e. conversion of timberland to residential development eliminates the possible use of the site for future timber production, conversion to farmland, etc.).

No-Action Alternative

SEPA requires the evaluation of the no-action alternative, which at times may be more environmentally costly than the proposal, or may not be considered “reasonable” by other criteria. Still, it provides a benchmark from which the other alternatives can be compared.

The identification of a no-action alternative can sometimes be difficult. It is typically defined as what would be most likely to happen if the proposal did not occur. If a rezone is proposed, what is the most likely development on the site under existing zoning? If the proposal involves conversion of forestland to another use, this can be compared to the impacts of continued use of the site for timber production.

There are other methods of defining the no-action alternative, such as “no new government action,” or the “lock the gate and walk away” scenario where all current activities are also ceased. As the SEPA Rules do not define what the no-action alternative must look like, the lead agency has some discretion in its design

Preferred Alternative

SEPA does not require the designation of a “preferred alternative” in an EIS. By identifying a preferred alternative, reviewers are made aware of which alternative the lead agency feels is best or appears most likely to be approved. This can be helpful for public proposals when the purpose and objectives are more general.

Identifying a preferred alternative may also have disadvantages. The public may feel that the decision has already been made, which can cause frustration with the process. Also, comments received may be limited to arguments against the agency "decision," with supporters of the preferred alternative not bothering to respond at all. This may result in a lack of feedback both on the problems related to other "non-preferred" alternatives and on the benefits of the preferred alternative.

If used, the preferred alternative can be identified at any time in the EIS process—scoping, draft EIS, or final EIS. When designated early in the process, it should be expected that changes are likely to occur to the preferred alternative prior to issuing the final EIS. Early designation of a preferred alternative in no way restricts the lead agency’s final decisions.

Affected Environment, Significant Impacts, and Mitigation Measures

An EIS describes the existing environment that will be affected by the proposal, analyzes significant adverse environmental impacts of each alternative, and discusses reasonable mitigation measures. This discussion should be concise, not overly detailed, and should focus on those elements of the environment that will be significantly impacted. For example, it would be a rare necessity to describe the impacts of the Ice Age on the project site. However, if the type of soil will affect the type of stormwater control needed for the site, the EIS should identify the type of soil on the site (affected environment), describe proposed stormwater controls (proposal), and identify other appropriate stormwater controls (mitigation measures).

When describing the environmental impacts of a proposal, the lead agency should consider direct, indirect, and cumulative impacts. For example:

- A new residential development may propose to place fill in a wetland in order to construct a road (a direct impact).
- The new road will encourage increased development in the area because of the improved access (an indirect impact).
- Increased runoff and contaminants from the development would be added to the volumes and levels of contamination from similar developments surrounding the wetland (cumulative impacts).

Impacts can be temporary, such as the short-term impacts associated with the construction phase of a proposal, or permanent, such as the long-term impact of increased runoff and contamination from a widened roadway. Both should be considered when identifying significant adverse environmental impacts to be analyzed in the EIS.

Mitigation is defined as avoiding, minimizing, rectifying (repairing), reducing, eliminating, compensating, or monitoring environmental impacts (see WAC 197-11-768). Mitigation may be suggested by the applicant; mandated by local, state, and federal regulations; or required through the use of SEPA Substantive Authority. (See Using SEPA in Decision Making section)

The EIS should identify possible mitigation measures that will reduce or eliminate the adverse environmental impacts of a proposal. The discussion should include information on the intended environmental benefit of the proposed mitigation as it relates to the identified impact. If the technical feasibility or economic practicality is uncertain, the mitigation measure may still be discussed but discussion of the uncertainties should be included. The EIS should also clearly identify the mitigation measures as either mandatory or as potential so reviewers may better assess the impacts of the proposal.

Mitigation measures must be reasonable and capable of being accomplished. The applicant may be required to implement mitigation measures only to the extent attributable to the identified adverse impacts of the proposal.

EIS Summary Section

The summary section, which should be at the beginning of the EIS text, is the portion most likely to be read by decision-makers and members of the public. It should include a summation of the main issues in the EIS, including a concise description or discussion of:

- the proposal,
- the proposal's objective
- purpose and need
- environmental impacts,
- alternatives,
- mitigation measures, and
- significant adverse impacts that cannot be mitigated.

The summary should also identify: (1) the major conclusions and significant areas of controversy, and (2) any remaining uncertainties and issues to be resolved. The discussion is useful because it presents the proposal as a whole, rather than separated by individual

element.

Matrices and charts, although not required, can be useful for summarizing alternatives, impacts and mitigation measures. See WAC 197-11-440(4) for additional detail.

Other (non-environmental) impacts, such as a cost/benefit analysis, may be included in the EIS if the lead agency determines this information would be helpful in evaluating the proposal.

Draft EIS

A draft EIS documents the lead agency's analysis of a proposal, and provides an opportunity for agencies, affected tribes, and the public to review the document and provide suggestions for improving the adequacy of the environmental analysis.

Comments on the draft EIS stimulate discussion and thoughts about how to change or condition the proposal to further protect the environment. Lead agency review of those comments offers the opportunity to improve the completeness, accuracy, and objectivity of the environmental analysis of a proposal. Improvements can then be made in the final EIS that will provide information to decision-makers. In some cases, the proponent may choose to modify the proposal based on comments made during the draft EIS comment period. In that instance, the modifications would also be described and evaluated in the final EIS.

Issuing a Draft EIS

When the lead agency is satisfied with the content of the draft EIS, the EIS is issued and is circulated for review (see WAC 197-11-455 for specific requirements). The lead agency must also give public notice, and is encouraged to send a notice of availability or a copy of the draft EIS to anyone that has expressed an interest in the proposa1. Reviewers then have the opportunity to comment on the accuracy and completeness of the environmental analysis, the methodology used in the analysis, and the need for additional information and/or mitigation measures, so that improvements to the EIS can be made before it is finalized.

A 30-day comment period is required on the draft EIS. The lead agency may extend the comment period up to an additional 15 days without consulting the applicant. The lead agency will sometimes include the additional days in the comment period when the EIS is issued, or they may grant an extension of the comment period on request. When an extension of the comment period is granted, the lead agency should whenever feasible provide notice of the extension to other reviewers. (The lead agency is not required to provide this notice, and there are no requirements regarding how notice is given.)

When the lead agency is also the proponent of the proposal, the time periods may be extended to whatever the lead agency thinks is appropriate. The lead agency is required to hold a public hearing if 50 or more persons, within the agency’s jurisdiction or who would be adversely impacted by the proposal, make written request within 30 days of the issue date of the draft EIS. Lead agencies may also at their option provide this additional avenue

and opportunity for agencies, tribes, and the public to comment on the document. The hearing must be held between 15 and 50 days after the draft EIS is issued, and a minimum of 10-day notice must be made. If held, this hearing does not constitute the one open-record hearing that is allowed under RCW 36.70B.020(3).

Except when SEPA requires a document to be sent to an agency, lead agencies may charge for providing an EIS and related environmental documents[68]. Each agency should have policies regarding charges for requested documents. When requested by public interest organizations, agencies are encouraged to provide environmental documents free of charge.

Final EIS

The final EIS provides decision-makers with environmental information about a proposal to help them decide whether to approve the proposal, approve it with conditions (mitigation), or deny the proposal. It is the lead agency's record of the environmental analysis conducted for the proposal. The final EIS includes information and input from the applicant, lead agency, other agencies with jurisdiction or concern, tribes, and the public regarding the proposal. It is completed early enough so that there is still a choice between reasonable alternatives.

Responding to Comments on the Draft EIS

The lead agency must consider comments received during the draft EIS comment period, and respond to them in the final EIS. Lead agency responses to comments should be as specific and informative as possible. Possible responses are to:

- Explain how the alternatives, including the proposed action, were modified;
- Identify new alternatives that were created;
- Explain how the analysis was supplemented, improved, or modified;
- Make factual corrections; or
- Explain why the comment does not warrant further agency response.

All timely and substantive comments and the lead agency's responses to them must be included in an appendix in the final EIS. If repetitive or voluminous, the comments may be summarized and the names of the commenters included. The lead agency may respond to each comment individually, respond to a group of comments together, cross-reference comments and the corresponding changes in the EIS, or any other reasonable method to provide an appropriate response.

Tip: If the comment is generic or nonspecific (e.g., "There will be unacceptable air quality impacts"), the response might be: "Your comment was considered but it was not specific or applicable enough to respond to. Please see Section XX of the final EIS for a discussion of air quality impacts and possible mitigation."

Timing of Final EIS

The final EIS is intended to follow closely after the draft EIS, if at all possible. The SEPA Rules state that a final EIS shall be issued within 60 days after the end of the comment period for the draft EIS, except when:

- the proposal is unusually large in scope;
- the environmental impacts are unusually complex; or
- responding to the draft EIS comments requires extensive modifications to the EIS and/or the project.

Format of Final EIS

After considering comments on the draft EIS, the lead agency has several options for completing the EIS:

- If there are no substantial comments or changes proposed on the draft EIS, the lead agency may state that in an updated fact sheet. The final EIS is then composed of the draft EIS with the new fact sheet attached.
- If changes to the draft EIS are minor (e.g. response to comments involves factual corrections or an explanation that the comment does not warrant additional consideration), an "addendum" may be prepared. In this case, the final EIS consists of the draft EIS, a new fact sheet, and the attached addendum. The addendum must contain the comments received on the draft EIS, the lead agency's responses, and any changes to the information and analysis in the draft. Previous recipients of the draft EIS need only be sent the new fact sheet and the addendum.
- If there are substantive comments that warrant substantial changes to the EIS, the final EIS is typically issued with a similar format to the draft. The draft EIS comments together with the lead agency's responses (see Responding to Comments on the draft EIS) are included as an appendix, and the necessary changes are made throughout the EIS text. Using a similar format for both the draft and the final EIS makes the two documents easier to compare.
- If any significant new issues have been raised, the lead agency may choose to issue a supplemental draft EIS with a second comment period prior to issuing the final EIS. This allows the public, tribes, and other agencies to review and comment on the new material and analyses before the document is finalized. (See the following Supplementing an EIS for additional discussion.) The final EIS, when it is ultimately issued, may have any of the above formats.

Issuing a Final EIS

The final EIS is distributed to the Department of Ecology (two copies), all agencies with jurisdiction, any agency who commented on the draft EIS, and (though a fee may be charged) to any person requesting a copy. The final EIS or a notice that it is available must also be sent to anyone who had commented or received the draft EIS. Agencies may take an action/make a decision on the proposal seven days after the final EIS has been issued.

Supplementing an EIS

A supplemental EIS adds information and analysis to supplement the information in a previous EIS. It may address new alternatives, new areas of likely significant adverse impact, or add additional analysis to areas not adequately addressed in the original document. When the additional information is minor and does not involve the analysis of

new significant impacts, an addendum may be issued.

A supplemental EIS includes a draft (with comment period) and a final document, which essentially follows the same requirements as a draft EIS and final EIS. Scoping for a supplemental EIS is optional.

The supplemental EIS process is normally used after a draft and final EIS have been issued. However, a supplemental draft EIS may be issued before a final EIS if there are significant changes in the draft EIS. In this case, the draft EIS is circulated for review, then a supplemental draft EIS is circulated for review, and a final EIS is issued which responds to comments on both the draft and supplemental draft EISs.

There are several situations when a supplemental EIS is appropriate:

- The proposal has changed and is likely to cause new or increased significant adverse environmental impacts that were not evaluated in the original EIS.
- New information becomes available indicating new or increased significant environmental impacts are likely.
- The lead agency decides that significant issues/impacts were missed in the draft EIS and/or additional alternatives or mitigation should be evaluated and SEPA goals would be better served with another draft EIS and comment period.
- The original EIS was issued for a different proposal (such as a comprehensive plan), but provides the basis for review of the current proposal. In this instance, the original EIS is adopted and the adoption form must be included within the draft supplemental EIS, which contains analysis of any likely significant adverse environmental impacts not yet evaluated.
- An agency with jurisdiction concludes its comments on the draft EIS were not adequately addressed in the lead agency's final EIS. In this case, the agency with jurisdiction must prepare the supplemental EIS at their own expense.

Tips:

- To facilitate review and the comparison of options, it is helpful for the supplemental EIS to use the same organization and format as the original EIS.
- When a supplemental EIS is being prepared after the final EIS is issued, agencies with jurisdiction should consider waiting to issue permits until after the final supplemental EIS is issued. Although, the SEPA Rules do not address this, the additional analysis, changes to the proposal, or new mitigation may be relevant to other agencies' decisions. The agency preparing the document should notify all agencies with jurisdiction that a supplemental EIS is being prepared.

4. Nonproject Review

Nonproject actions are governmental actions involving decisions on policies, plans, or programs that contain standards controlling use or modification of the environment, or that will govern a series of connected actions. This includes, but is not limited to, the adoption or amendment of comprehensive plans, transportation plans, ordinances, rules, and regulations[77]. Any proposal that meets the definition of a nonproject action must be reviewed under SEPA, unless specifically exempted.

Nonproject review allows agencies to consider the "big picture" by conducting comprehensive analysis, addressing cumulative impacts, possible alternatives, and mitigation measures. This has become increasingly important in recent years for several reasons:

- **Provides the basis for future project decisions:** Environmental analysis at the nonproject stage forms the basis for later project review, providing greater predictability.
- **Expedites project analysis and decisions:** The more detailed and complete the environmental analysis during the nonproject stage, the less review needed during project review. Project review is able to focus on only those environmental issues not adequately addressed during the nonproject stage.

General Guidance for Nonproject Actions

The procedural requirements for SEPA review of a nonproject proposal are basically the same as a project proposal. Environmental review starts as early in the process as possible when there is sufficient information to analyze the probable environmental impacts of the proposal. The first step is usually to complete an environmental checklist (including Part D, Supplemental Sheet for Nonproject Activities), unless the lead agency has already determined that an environmental impact statement is needed or SEPA has already been completed.

Review of a nonproject proposal should include a consideration of other existing regulations and plans, and any under development. For example, during development of a critical area ordinance, the agency should consider the relationship to the Clean Water Act, Shoreline Management Act, and similar regulations.

If the nonproject action is a comprehensive plan or similar proposal that will govern future project development, the probable impacts need to be considered of the future development that would be allowed. For example, environmental analysis of a zone designation should analyze the likely impacts of the development allowed within that zone. The more specific the analysis at this point, the less environmental review needed when a project permit application is submitted.

Whenever possible, the proposal should be described in terms of alternative means of accomplishing an objective. For example, a statewide plan for use of chemicals to treat aquatic vegetation could be described as a plan to control aquatic vegetation. This would encourage the review of various alternatives for treating vegetation in addition to the use of chemicals. This might include a review of biological or mechanical methods, or a combination of the various methods. Environmental review of nonproject actions by GMA cities and counties have additional specific guidance and requirements.

Contents of a Nonproject EIS

In most instances, the development of a nonproject action (i.e. plan or policy) involves an

analysis of alternatives and the potential consequences of future project actions. Since an EIS also evaluates alternatives and probable impacts, it should be possible to combine the EIS with the analysis of the nonproject action and issue an integrated document.

Agencies have great flexibility in formatting a nonproject EIS and are encouraged to combine the EIS with the planning document. The EIS should discuss impacts and alternatives with the level of detail appropriate to the scope of the nonproject proposal. Although the format is flexible, the EIS must include a cover letter or memo, a fact sheet, a table of contents, and a summary.

In preparing a nonproject EIS the following areas should be considered for inclusion:

Background and Objectives

- Background of the issue, including the purpose and need for action.
- Legislative authority or mandate.
- Statement of the primary objective.
- Relationship to ongoing and future regulatory and planning efforts.

Existing Situation

- Description of the existing situation—current regulations, existing means of achieving the objective, current institutional structure.

Proposal and Alternatives

- Description of the proposed regulation, policy, plan, etc.
- Alternatives to the proposal which could reasonably meet the primary objective.

Environmental Impacts

- Summary of the adverse environmental impacts relative to other policies. For example, the consequences of the transportation plan on housing policy or plans.
- Summary of environmental impacts from the proposal and alternatives.

Tip: When preparing a nonproject environmental document, the lead agency should think about the use of the document during the environmental review of future project proposals. Will the information provide a solid foundation for additional analysis at the project phase? Will the information be easy to locate and cross reference in later environmental documents?

5. Agencies Role in Review & Commenting

An important part of SEPA is the opportunity for citizens and other agencies to review and comment on many proposals. When an opportunity to comment on a SEPA document is missed or ignored, the opportunity to have a beneficial effect on the proposal is often lost. Comments can provide the lead agency with missing information on the proposal, identify inaccurate information, and/or provide input on possible mitigation or alternatives.

It is vital that comments are filed with the lead agency before the comment period closes. Lack of timely comment by agencies or the public is construed as a lack of objection to the environmental analysis completed by the lead agency.

It is particularly important for agencies with jurisdiction to comment when they have concerns about a proposal. Since the comments become part of the SEPA record, the information can be used by any agency with jurisdiction when making permit decisions. (See section 6. **Using SEPA in Decision Making**). Additionally, the SEPA rules include a list of state agencies "with expertise" on each element of the environment. They should be consulted at the earliest opportunity to review a Checklist or other draft SEPA document.

When to Comment

Citizens and agencies are accustomed to commenting on project proposals where it is easy to see the potential for on-the-ground impacts. It has become increasingly important to also review and comment on nonproject proposals. These include the adoption of state or local rules, resource management plans, comprehensive plans, critical area ordinances, development regulations, etc. Plans and the implementing regulations are likely to have a much more widespread influence, as they may affect the permitting, approval, or denial of unknown numbers of future project proposals or permit renewals.

As more cities and counties are planning under the Growth Management Act, many environmental concerns are considered during the development of plans and implementing regulations. Many of these issues cannot be reconsidered or appealed during later project review.

Table 2 contains information on the public comment periods, public notice, and circulation requirements for SEPA documents. Although the majority of SEPA documents require a comment period, some do not. The following types of documents may provide opportunities to comment on a proposal, although no proposal—project or nonproject—will offer all:

If a consulted agency fails to comment on a draft EIS, the agency is barred from alleging any defect in the analysis in the EIS. A consulted agency is any agency with jurisdiction or expertise that is requested by the lead agency to provide information or comments on a proposal during the SEPA process.

If an agency with jurisdiction comments on a draft EIS and the lead agency does not provide adequate response to the concerns, the agency with jurisdiction may prepare a supplemental EIS.

6. Using SEPA in Decision Making

Substantive authority is an essential part of SEPA. It allows decision-makers to use the environmental analysis required under SEPA to condition or deny proposals.
One of the most important aspects of the SEPA process is the consideration of environmental impacts and possible mitigation measures during agency decision- making. SEPA substantive authority gives all levels of government the ability to condition or deny a proposal based on environmental impacts.

Mitigation must be included as permit conditions to be enforceable. The exception is when a proponent alters the permit application(s) to include the needed changes or conditions.

Identification of mitigation in a DNS or EIS alone is not sufficient to allow enforcement.

Before requiring mitigation measures under SEPA substantive authority, agencies are to first consider whether local, state, or federal requirements and enforcement would mitigate the identified significant adverse impacts.

Decision-makers should judge whether possible mitigation measures are likely to protect or enhance environmental quality. Mitigation measures must be related to a specific adverse impact clearly identified in an environmental document[86] on the proposal, and must be reasonable and capable of being accomplished.

When using SEPA substantive authority, the decision-maker must:

1. Cite the agency SEPA policy that is the basis for conditioning or denying the proposal;
2. Document the decision in writing; and
3. Make available to the public a document that states the decision, and any mitigation measures will be required. This document may be the permit, license, or approval; or it may be combined with other agency documents; or
4. the decision document may reference relevant portions of environmental documents.

To deny a proposal under SEPA, an agency must find that:

1. The proposal would be likely to result in a significant adverse environmental impact identified in a final EIS or final supplemental EIS; and
2. Reasonable mitigation measures are not sufficient to mitigate the identified impact to a non-significant level.

SEPA supplements the existing authority of all agencies. To exercise SEPA substantive authority each agency must adopt SEPA policies that will be the basis for conditioning or denying proposals. These policies must be readily available to the public for the benefit of applicants and concerned citizens. (See adoption procedures in WAC 197-11-902.)

7. SEPA and the Growth Management Act (GMA)

Environmental review at the planning stage allows the GMA city or county to analyze impacts and determine mitigation system-wide, rather than project by project. This allows cumulative impacts to be identified and addressed, and provides a more consistent framework for the review, conditioning, or denial of future projects.

Planned Actions

In 1995, the legislature authorized a new category of project action in SEPA called a “planned action.” Designating specific types of projects as planned action projects shifts environmental review of a project from the time permit application is made to an earlier phase in the planning process. The intent is to provide a more streamlined environmental review process at the project stage by conducting more detailed environmental analysis during planning. Early

environmental review provides more certainty to permit applicants with respect to what will be required and to the public with respect to how the environmental impacts will be addressed.

The GMA city or county must first complete an EIS which addresses the likely significant adverse environmental impacts of the planned action. After completing the EIS, the GMA city or county designates by ordinance or resolution those types of projects to be considered planned actions, including mitigation measures that will be applied. The types of project action must be limited to certain types of development or to a specific geographic area that is less extensive than a city or town's jurisdictional boundaries. (See RCW 43.21C.440, WAC 197-11-164 and 168 for requirements and restrictions on the designation of planned actions.)

While normal project review requires a threshold determination, a project qualifying as a planned action project does not require a new threshold determination. If the city or county reviews the project, verifies that it is consistent with the planned action project(s) previously designated, and determines that the impacts are adequately addressed in the EIS on which the planned action relies, project permit review continues without a threshold determination. All of the project's significant probable environment impacts must have been addressed at the plan level in order for the project to qualify as a planned action.

Designating planned action projects reduces permit-processing time. There are no SEPA public notice requirements or procedural administrative appeals at the project level because a threshold determination or new EIS is not required. The only notice requirements are those required for the underlying permit.

The designation of planned action projects will only be appropriate in limited situations. The designation of planned action projects is probably most appropriate for:

- Smaller geographic areas;
- Relatively homogenous geographic areas where future development types, site-specific conditions, and impacts can be more easily forecast;
- Development sites with significant overlapping regulatory requirements; or
- Routine types of development with few impacts.

Examples of appropriate project actions limited to a specific geographic area might be projects anticipated in a subarea or neighborhood plan with a limited number of development types. Another example could be a large parcel in single ownership, such as a university campus or a large manufacturing complex where project construction will be done in phases.

Designating Planned Action Projects

The basic steps in designating planned action projects are to prepare an EIS, designate the planned action projects by ordinance or resolution, and review permit applications for projects proposed as consistent with the designated planned action.

Step 1: Prepare the EIS

The significant environmental impacts of projects designated as planned actions must be identified and adequately addressed in an EIS. The EIS must be prepared for a GMA

comprehensive plan or subarea plan, a master planned development or resort, a fully contained community, or a phased project.

Planned action projects should only be designated when a county or city can reasonably analyze the site-specific impacts that will occur as a result of the types of projects designated, and can adequately address those impacts in the EIS. A generalized analysis of cumulative environmental impacts will not provide enough information to address a project's impacts when it is time for the jurisdiction to issue permits for specific projects proposed as planned action projects.

Step 2: Adopt Planned Action Ordinance or Resolution

Planned action projects must be designated or identified in an ordinance or resolution adopted by a GMA county or city. There are a number of procedural requirements for this. A GMA county/city considering the adoption of a planned action ordinance or resolution should review the requirements in RCW 43.21C.440 and WAC 197-11-164, 168, and 315. The following specific points should be considered:

- An extensive level of public review for both the EIS and the proposed planned action ordinance is crucial. Since a new threshold determination or EIS is not required when a permit application is received, there may not be an opportunity for public review or administrative appeal at the project review stage. In order to build support for an abbreviated permit process, public awareness is needed at these earlier phases.
- Although the statute allows a jurisdiction to designate planned action projects by an ordinance or resolution, adoption by resolution is not recommended. The provisions for adoption of a resolution do not allow sufficient opportunity for public participation.
- The planned action ordinance should be as specific as possible, should indicate where in the EIS or associated planning document the projects' environmental impacts have been addressed, and should include or reference mitigation measures which will be required for a project to qualify as a planned action project. For example, the ordinance should indicate what mitigation has been identified in the EIS or what level of service has been accepted in the subarea plan for traffic impacts.
- If desired, the city or county may set a time limit in the ordinance during which the planned action designation is valid. If a GMA county/city does set a time limit on the designation, it should consider how this affects any permits for which there is an expiration date. For example, a project with a permit valid for five years is found to qualify as a planned action project and the permit is issued just prior to the sunset date for the planned action designation. Is the project still considered a planned action project for the life of the permit after the sunset date?
- Although a GMA county or city must require the applicant to submit a SEPA environmental checklist with a project proposed as a planned action project, a revised format for the checklist may be developed by the city or county. A draft of

the revised form must be sent to Ecology for a thirty- day review[105]. While not required at this phase, it would be helpful if the revised checklist were developed in conjunction with the ordinance or resolution designating planned action projects.

Step 3: Review the Proposed Planned Action Project

When a permit application and environmental checklist are submitted for a project that is being proposed as a planned action project, the city or county must verify:

- The project meets the description of any project(s) designated as a planned action by ordinance or resolution;
- The probable significant adverse environmental impacts were adequately addressed in the EIS; and
- The project includes any conditions or mitigation measures outlined in the ordinance or resolution.

If the project meets the above requirements, the project qualifies as a planned action project. Neither a threshold determination nor an EIS will be required. Consequently, there will be no administrative SEPA procedural appeal (an appeal of whether the proper steps in the SEPA process were followed). The planned action project will continue through the permit process pursuant to any notice and other requirements contained in the development regulations.

If the project does **not** meet the requirements of the planned action ordinance or resolution, or if the EIS did not adequately address all probable significant adverse environmental impacts, the project is not a planned action project. In this instance, the city or county must then make a threshold determination on the project. The project would go through normal environmental review as part of project review. The county or city may still rely on the environmental information contained in the EIS and supporting documents in analyzing the project's environmental impacts and making the threshold determination. If an EIS or SEIS is found to be necessary for the project, it only needs to address those environmental impacts not adequately addressed in the previous EIS.

Consistency Requirements for Planned Action Projects

A project proposed as a planned action project must still be analyzed for consistency with the local comprehensive plan and development regulations (see section on **Analyzing Consistency**). Designation of planned action projects does not limit a city or county from using other authority (e.g. transportation mitigation ordinances) to place conditions on a project; it only addresses procedural SEPA requirements. The GMA county or city may still use its SEPA substantive authority or other applicable laws or regulations to impose conditions on a project qualifying as a planned action project.

8. GMA and SEPA: Local Project Review Act

The Local Project Review Act was part of the Land Use Regulatory Reform Act signed into law in 1995 (ESHB 1724, codified in Chapter 36.70B RCW). It requires counties and cities to combine permit review and environmental review, and to consolidate administrative appeals of

permit and SEPA decisions. Integrated project review can provide a more streamlined permit and environmental review process for proposals projected in the comprehensive plan.

Requirements for Integrated Project Review

Counties and cities planning under GMA have additional requirements that must be adopted by ordinance or resolution. The following steps must be included in their project review process:

- Determination of Completeness
- Notice of Application
- Notice of Decision–issued within 120 days of the Determination of Completeness
- Combined permit and SEPA administrative appeals

There have been a number of questions on whether the project review requirements in Chapter 36.70B RCW apply to comprehensive plan or development regulation amendments, such as rezones. Comprehensive plan and development regulation amendments are nonproject actions and therefore not subject to project review requirements. Amendments to the comprehensive plan and development regulations are nonproject regardless of whether they are initiated by the county or city or by citizen request, however, in all instances they remain subject to SEPA and GMA requirements for public review and comment.

Steps in the *Project Review* Process for GMA Counties and Cities

Non-GMA cities and counties may also choose to follow this process for integrating their permit and environmental review procedures.

Preapplication Process
A preapplication process can be beneficial to the applicant and to reviewing agencies. The process usually involves a meeting between the applicant, various county or city departments, and other agencies that issue permits. A preapplication meeting allows the applicant to discuss the project and gather information on what studies and mitigation may be required. The county or city has an opportunity to inform the applicant whether the project appears to be consistent with the development regulations and/or comprehensive plan, and to identify any environmental studies or mitigation that may be required.

Determination of Completeness
Counties and cities planning under GMA are required to determine whether an application is complete enough to begin processing within 28 days of submittal. If the application is determined complete, it is documented in a "determination of completeness" and sent to the applicant. If the application is not complete, the GMA county or city may request additional information from the applicant. Once this information is submitted, the agency has 14 days to determine whether the application is now complete and to notify the applicant in writing.

Even though a county or city has determined an application to be complete, it is not precluded from later requesting additional information or studies.

SEPA considerations at this stage of project review:

Is SEPA review required? If this is the first permit application submitted for a proposal, the county or city will also determine whether the proposal is categorically exempt (or whether SEPA has already been completed). If SEPA review is not required, the county or city must still comply with the requirements of the Local Project Review Act.

Who is lead agency? In most instances, the county or city will be the lead agency. However, the county or city will not be the lead agency when another agency is the proponent or is designated lead under the SEPA Rules for a specific type of proposal (see WAC 197-11-938). If the county or city is not the lead agency, it will still analyze the consistency of the project with applicable development regulations and/or comprehensive plan policies. That information should be provided to the lead agency.

What if the lead agency is also the project proponent? When there is a public proposal, such as a road project or sewer system, the proponent is usually the SEPA lead agency. Public proposals often take several years to plan and implement. The public agency proponent usually does its environmental review under SEPA months or years prior to submitting a permit application to the county or city. The Local Project Review Act and SEPA were amended in 1997 to allow a public agency that is funding or implementing a proposal to conduct its environmental review and complete procedural appeals under SEPA prior to submitting a permit application.

Other issues to consider:

- Issues that should be considered during initial project review by GMA counties or cities include the following:
- Is the project description complete? Is the project properly defined? Have all interdependent pieces of the project been identified? (See WAC 197-11-060(3))
- Is the project consistent with the development regulations, or in the absence of applicable development regulations, the comprehensive plan? (See RCW 36.70B.030 and 040, and the section below on Analyzing Consistency.)
- Are specific studies needed under the development regulations and/or SEPA environmental review, or by other local, state, or federal regulations (e.g., a wetland study, transportation study, etc.)?
- What are the environmental impacts of the proposal? Have they been addressed by existing environmental documents (for example, an EIS on the comprehensive plan or an EIS on a similar project or located in a similar geographic area)?
- Will mitigation/conditions be required by the development regulations; or other local, state, or federal regulations?

Are there environmental impacts that have not been addressed by the regulations? It may not be possible to answer all of these questions during the initial review phase, but it is important to consider them as early in the review process as possible.

Notice of Application (NOA)

The determination of significance (DS/Scoping notice) may be combined with the NOA if a GMA county or city is also lead agency under SEPA and has determined an EIS is needed at the time it issues the notice of application. The county or city may also issue the DS and scoping notice prior to issuing the notice of application, or they may wait to consider comments received on the NOA before making a threshold determination.

Optional DNS

The optional DNS process gives GMA counties and cities the flexibility to consolidate the notice and comment process prior to issuing the DNS. When the GMA city or county is the SEPA lead agency for a proposal and they have completed their environmental review at the time they will issue the NOA, they may choose to use the optional DNS process and receive comments on the Checklist prior to formal issuance of the DNS –which occurs with the Notice of Decision.

With the optional DNS process, the agency solicits comments on environmental issues during the NOA comment period. Reviewing agencies and the public are warned that they may have only the one opportunity to comment on the proposal. Later, when the DNS is formally issued at the end of the NOA comment period, the lead agency is not required to provide a second comment period.

A GMA county or city should consider the following points before deciding to use the optional DNS process:

- It is intended for minor projects that can be fully reviewed prior to issuing a NOA. If the proposed project is more complex, or environmental review cannot be completed within the time limits for the NOA, the regular DNS process should be used.
- The NOA must contain sufficient information on the proposed project, including proposed mitigation measures, to allow other agencies and the public to understand the proposal and comment on any areas of concern. This is particularly important since this is likely to be the only opportunity for the other agencies and public to comment on the probable impacts of the proposed project. It is also the only time that other agencies with jurisdiction will have the opportunity to assume lead agency status.
- A DNS may be issued at the time of NOA and avoid the need for the optional process because the comment period for SEPA automatically coincides with the NOA comment period.

If the optional process is being used, the county or city must state on the first page of the NOA that:

- The optional DNS process is being used;
- The agency expects to issue a DNS for the proposal; and
- This may be the only opportunity to comment on the environmental impacts of the proposed project.
- The NOA and the environmental checklist are distributed to agencies with jurisdiction or expertise, affected tribes, and the public.

After the close of the comment period on the NOA, the agency reviews any comments on the environmental impacts of the project and decides whether to proceed with issuing a DNS. The choices at this point are:

- Issue a DNS without an additional comment period;
- Issue a DNS with a second comment period;
- Issue a DS; or
- Require additional information or studies prior to making a threshold determination.

The lead agency is required to circulate the DNS, if issued, to the Department of Ecology, agencies with jurisdiction, anyone who commented on the NOA, and anyone requesting a copy.

If the lead agency uses the optional DNS process, an agency with jurisdiction may assume lead agency status during the comment period on the notice of application.

Notice of Final Decision

Once the public comment period on the notice of application ends, the agency will review the comments and complete the project review process, including environmental analysis. At the end of the review, a notice of final decision on the permit is issued. The county or city may include permit conditions in the notice of decision based on the development regulations or under the jurisdiction's SEPA substantive authority. (See **Using SEPA in Decision Making**)

9. SEPA's Relation to NEPA

Each federal agency must adopt its own procedures to meet the requirements and intent of NEPA. The review process of each agency will therefore vary. In general, the NEPA process includes the preparation of an environmental assessment (EA) followed by either a finding of no significant impact (FONSI) or by preparation of an environmental impact statement (EIS).

The EA contains information about the proposal that the lead agency uses to decide whether to prepare an EIS or a FONSI. It includes a description of the proposal, a discussion of the proposal's purpose and need, and identification of probable environmental impacts and possible alternatives. In some cases, the EA is circulated for public review and comment before the lead agency issues either a FONSI or an EIS.

The NEPA EIS process is much like the EIS process under SEPA: starting with scoping, then issuance of a draft EIS, and finally the preparation of a final EIS. After completion of the EIS, the federal agency usually issues a record of decision that includes the decisions made, the alternatives considered, and the factors that were considered in reaching a decision.

Integrating NEPA and SEPA

Some projects may require approval from both federal agencies and state or local agencies, thus requiring compliance with both NEPA and SEPA. For example, a major dredging operation might need approvals from the U.S. Corps of Engineers, Washington Department of Ecology,

and from the county or city. Since both federal and state/local licenses are required, compliance with both NEPA and SEPA would be needed.

SEPA's purpose and goals are almost identical but federal agencies may have procedures for environmental review (aside from the list of categorical exclusions) that are not fully aligned with SEPA requirements. The main areas of divergence could include the scope of the review, types of impacts and range of alternatives. SEPA provides an expressed substantive provision that authorizes agencies to deny or condition a proposal based upon the impacts addressed in the environmental documents. RCW 43.21C.060. This affords agencies and the public with an important purpose and need for SEPA review regardless of the extent of NEPA review established by the lead federal agency.

Proposals covered under a specific NEPA exclusion but also involve "agency actions" by state or local agencies – may require SEPA review. The environmental review requirements under SEPA are separate and independent from those required or exempted under NEPA. Both the process and criteria are different for establishing and applying exemptions under each statute and their implementing regulations.

1. NEPA EA/FONSI is completed first and the SEPA lead agency issues a DNS and "adopts" the EA in lieu of preparing an Environmental Checklist. A minimum 14-day SEPA comment period is required and additional information and analysis can be included in the DNS or added to the EA in the form of an Addendum. This option often involves close coordination between the NEPA and SEPA lead agencies to ensure that the NEPA analysis is sufficient for SEPA purposes;

2. NEPA EIS is completed first and the SEPA lead agency issues a DS and adopts the EIS in lieu of preparing a separate EIS. Technically the ROD does not have to have been issued prior to adoption under SEPA, however the NEPA EIS cannot have been found "inadequate" by a court, EPA or CEQ.

3. NEPA and SEPA processes are concurrent and a joint NEPA/SEPA EIS or a combined EA/FONSI/DNS is issued by the relevant "cooperating" agencies; or

4. NEPA documents and SEPA documents are issued independently and no adoption of previously prepared NEPA documents is involved.

Additionally, a "documented categorical exclusion" can also be adopted under SEPA when issuing a DNS, in lieu of preparing a Checklist –as long as all of SEPA's environmental elements have been adequately addressed in the NEPA documentation.

Federal public projects are considered "private" proposals for the purpose of determining the SEPA "lead agency." Local government agencies are typically designated as the SEPA lead for private projects if there is a corresponding local permit or approval for the project.

The table below compares NEPA and SEPA terms and procedural requirements:

NEPA	SEPA
Categorical Exclusion (CE), 40 CFR 1508.4, 40 CFR 1507.3	Categorical Exemption, WAC 197-11-800-880.Statutory Exemptions, RCW 43.21c
Environmental Assessment, 40 CFR 1508.9, 40 CFR 1501.3	Environmental Checklist, WAC 197-11-960,
Finding of No Significant Impact, 40 CFR 1508.13	Determination of Nonsignficance (DNS), WAC 197-11-340.
Notice of Intent, 40 CFR 1508.22	Determination of Significance (DS) and Scoping notice. WAC 197-11-360.
Draft Environmental Impact Statement (DEIS), 40 CFR 1502, 40 CFR 1508.11 Review	Draft Environmental Impact Statement (EIS), WAC 197-11-455.
Final Environmental Impact Statement (FEIS), 40 CFR 1502, 40 CFR 1508.11	Final EIS (FEIS), WAC 197-11-460.
Supplemental EIS,	Supplemental EIS,
Record of Decision, 40 CFR 1505.2	Agency decision – but SEPA agencies must wait seven days before taking action. WAC 197-11-460

10. SEPA and MTCA

In 1988, citizens passed Initiative 97, creating the Model Toxics Control Act (MTCA). An amendment to the SEPA statute in 1994 directed the integration of the review requirements of MTCA and SEPA. To meet this directive, several sections were added to the SEPA Rules that contain procedures to combine the MTCA and SEPA processes to reduce duplication and improve public participation.

WAC 197-11-250 through 268 apply to interim and final hazardous site cleanup activities conducted by the Department of Ecology, or by a potentially liable party under an order, agreed order, or decree. They do not apply to independent cleanup actions (which are reviewed under the normal SEPA process). If the Department of Ecology is not SEPA lead agency, the SEPA/MTCA integration procedures are used to the extent practicable.

11. Appeals

SEPA provides a process for citizens and other agencies to challenge both procedural and substantive decision made using SEPA review. **Procedural appeals** include the appeal of a threshold determination—both determinations of significance (DS) and nonsignificance (DNS)—and of the adequacy of a final environmental impact statement (EIS). **Substantive appeals** are challenges of an agency's use (or failure to use) SEPA substantive authority to condition or deny a proposal.

Appeals may also be heard at two levels:

- **Administrative appeals**, heard by agencies; and
- **Judicial appeals**, which are heard by courts when the administrative appeal process is either not available or has been exhausted.

Administrative appeals are not required but some local agencies provide this process and appellants must complete this process prior to pursuing a judicial challenge. Not all agencies provide an administrative appeal process, or they may provide for a substantive appeal or a procedural appeal but not both. In some situations, the first appeal may be a judicial appeal filed in superior court.

For more information on the SEPA appeal process, refer to RCW 43.21C.060, 075, and 080; and WAC 197-11-680. Also refer to the Local Project Review Act (Chapter 36.70B RCW), since it contains provisions relating to SEPA administrative appeals. Anyone interested in appealing a SEPA procedural issue should contact the lead agency to determine what administrative appeal, if any, will be allowed. Questions on the availability of administrative appeals for substantive decisions should be directed to the agency that made the decision (i.e. to deny, condition, or not to condition a permit or other approval).

Administrative Appeals

Each agency must decide whether or not to offer administrative appeals. If an agency offers an administrative appeal, the agency must specify its appeal procedure by ordinance, resolution, or rule.

An agency may provide appeals of some, but not all, reviewable SEPA decisions. The only decisions that may be appealed at the agency level are a final threshold determination or EIS (including a final supplemental EIS), and SEPA substantive decisions. Other decisions, for example the applicability of categorical exemptions, may only be appealed to the courts.

A DS, DNS, or EIS are each subject to a single administrative appeal proceeding. Successive reviews within the same agency are not allowed. For example, a hearing examiner's decision on the appeal of a DS cannot be further reviewed by the local legislative body. Further consideration is limited to review by a court as part of a judicial appeal.

Procedural and substantive SEPA appeals in most instances must be combined with a hearing or appeal on the underlying governmental action (such as the approval or denial of a permit). If a SEPA appeal is held prior to the agency making a decision on the underlying action, it must be heard at a proceeding where the person(s) deciding the appeal will also be considering what action to take on the underlying action.

SEPA appeals that do not have to be consolidated with a hearing or appeal on the underlying action are related to:

- A determination of significance (DS);
- An agency proposal;
- A non-project action; or
- The appeal of a substantive decision to local legislative bodies.

A local agency must also decide whether or not to allow an appeal of a non- elected official's decision to use SEPA substantive authority to condition or deny a proposal. If a local agency

chooses not to allow an appeal to a local legislative body, the agency must clearly state that decision in its procedures.

Judicial Appeals

Judicial appeals are those appeals heard in court. A judicial appeal in most instances must be of the underlying governmental action (permit decision, adoption of a regulation, etc.) and the SEPA document (DNS or final EIS). (Information on exceptions is given on page 110.) If the agency allows a SEPA administrative appeal, it must be used prior to initiating judicial review.

The time period for filing a judicial appeal will depend on several factors:

- **Time limit on the underlying governmental action** (issuance of permit, adoption of a plan, etc.). If there is a time limit established by statute or ordinance for appealing the underlying governmental action, then appeals raising SEPA issues must be filed within that time period. (see RCW 43.21C.075(5) for additional information.)
- **Time limit when publication of notice of action taken.** If there is no time limit for appealing the underlying governmental action, the notice of action provisions in RCW 43.21C.080 may be used to establish a 21-day appeal period.
- If there is **no time limit** for appealing the underlying governmental action and the notice of action is not used, then SEPA does not provide a time limit for judicial appeals. However, the general statutes of limitation or the common law may still limit appeals.

12. Adopting Agency SEPA Procedures and Policies

Each state and local agency must adopt its own rules and procedures for implementing SEPA. These “agency SEPA procedures” must be formally designated by rule, ordinance, or resolution. Before adopting their agency SEPA procedures, the agency must provide public notice and an opportunity for public comment.

An agency's SEPA procedures identify the agency's responsible official, the method(s) for public notice, the procedures for administrative appeal, if any, and other information about the agency's review procedures. If an agency does not adopt agency SEPA procedures, the defaults in the SEPA Rules will apply. For example, if the agency has not identified procedures for public notice, the agency must publish notice for SEPA documents in a newspaper of general circulation and post the site (for site-specific proposals). Another example is the administrative appeal process. To offer an administrative appeal of procedural and/or substantive issues, an agency must specify their administrative appeal process in their agency SEPA procedures.

Agencies have the option of adopting sections of the SEPA Rules by reference. This allows an agency to list the section title and a brief summary without repeating the entire text of the section. If incorporation by reference is used, the agency must have at least three copies of the full text of the SEPA Rules on file for public review.

Each agency must also adopt policies that will be used as the basis for conditioning or denying an action using SEPA substantive authority. These "agency SEPA policies" must be formally designated by rule, ordinance, or resolution, and may be part of the agency's SEPA procedures.

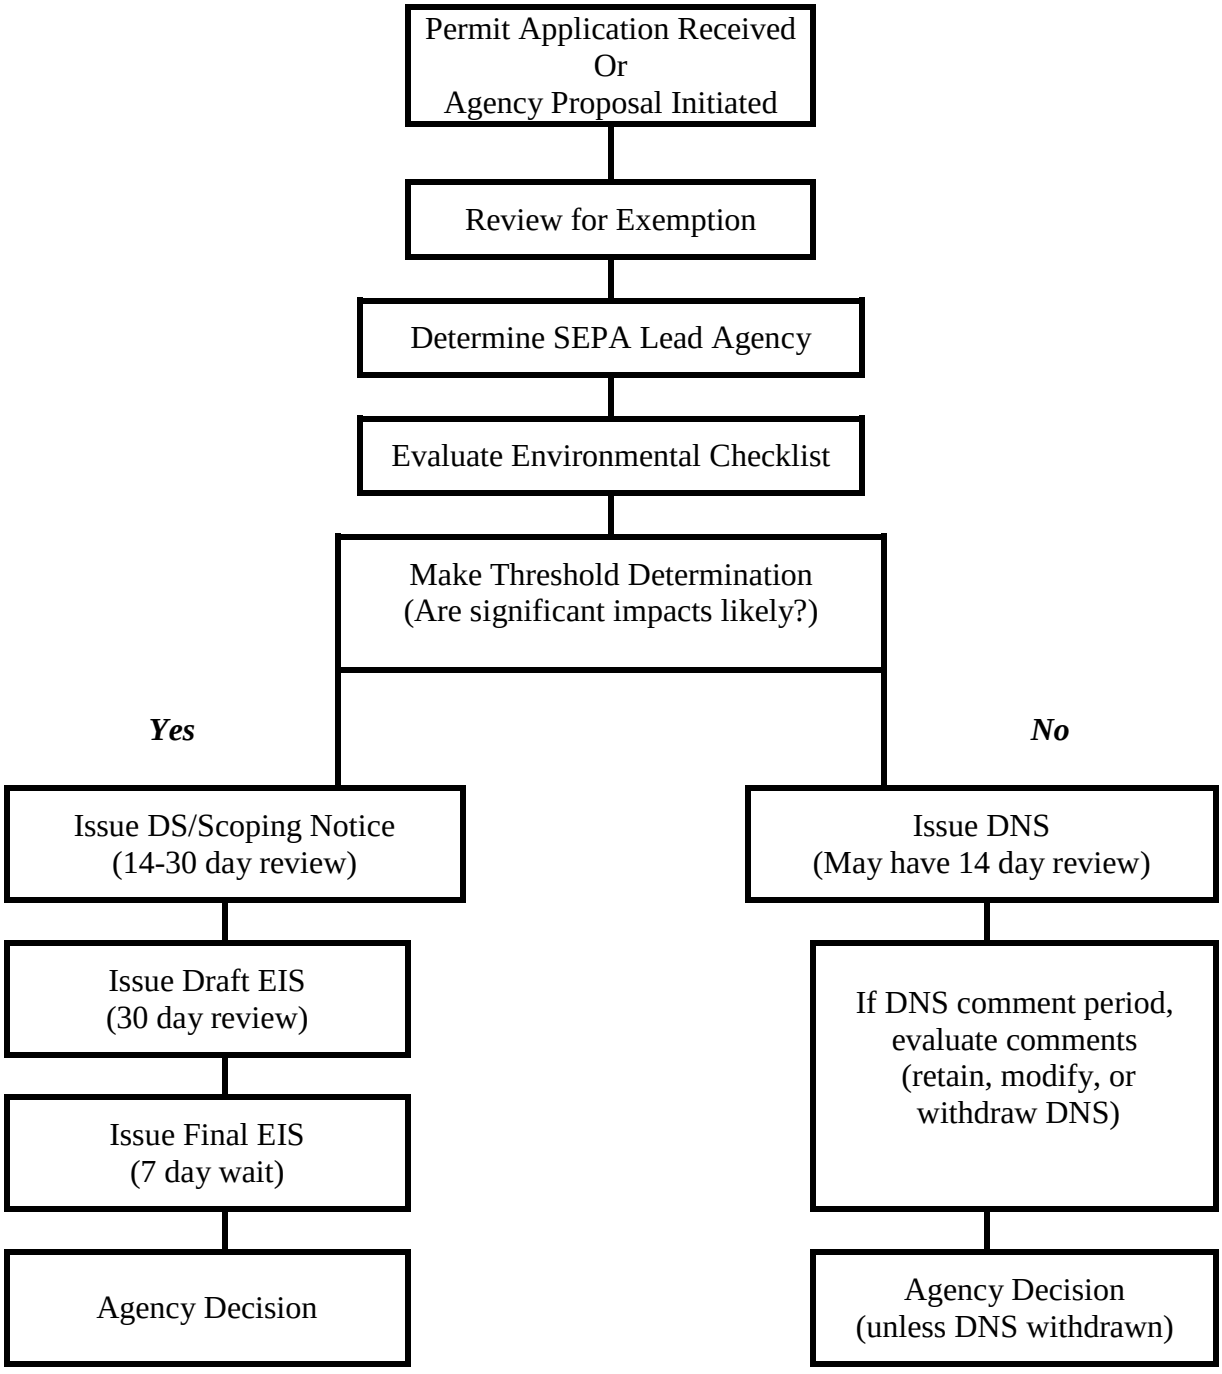
If an agency does not adopt SEPA policies, the agency cannot use SEPA substantive authority to condition or deny an action.

WAC 197-11-900 through 918 contains specific requirements for agency SEPA procedures and SEPA policies. WAC 197-11-906 specifically identifies provisions of the SEPA Rules that an agency cannot change or add to, and those that an agency cannot change but can add to (provided any additions are consistent with SEPA).

Examples of mandatory provisions that cannot be added to or changed include:

- Definitions of "proposal," "action," "significant," "mitigation," "etc.;
- Criteria for determining lead agency;
- Information required from applicants; and
- Style and size of an EIS.

Examples of provisions that cannot be changed but can be added to include:



- Part 4 (of the SEPA Rules), Environmental Impact Statement;
- Part 5, Commenting; and
- The list of agencies with environmental expertise.

Examples of provisions that are optional include:

- Establishment of an administrative appeal procedure;
- Elimination of some categorical exemptions in critical areas (counties and cities only);
- Establishing the categorical exemption level for minor construction within the minimum and maximum specified in the SEPA Rules (counties and cities only); and
- Specifying procedures for enforcement of mitigation measures.

An agency may amend it agency SEPA procedures at any time. If the agency's SEPA procedures change after the review of a proposal has started, the revised procedures will apply to any portions of SEPA that have not yet been started. For example, if a permit application and checklist are submitted before the new agency SEPA procedures become effective but the threshold determination is not made until after the effective date, the revisions would apply to the threshold determination but would not affect the checklist. The amended procedures cannot be used to invalidate or require modification of a threshold determination or EIS.

Re: Complaint under Title VI of the Civil Rights Act of 1964, 42 U.S.C. § 2000d, regarding the North Carolina Department of Environmental Quality's Issuance of Permit Nos. AWI310035, AWI301139, AWI230466, and AWS820005

Dear Administrator Regan and Director Dorka:

On behalf of the Duplin County Branch of the North Carolina Conference of the National Association for the Advancement of Colored People ("Duplin County NAACP") and the North Carolina Poor People's Campaign (together, "Complainants"), the Southern Environmental Law Center submits this complaint against the North Carolina Department of Environmental Quality ("DEQ") for its issuance of four permits ("Permits") authorizing swine waste management systems that lack necessary protections against air and water pollution at four industrial hog operations (together the "Hog Operations") in Duplin and Sampson Counties in rural eastern North Carolina.[1] A disproportionate share of the families who live around these operations are Black and Latinx. [2]

[1] *See* DEQ, Waters Farm-M&M Rivenbark Farm Permit No. AWI310035 (March 31,2021), https://files.nc.gov/ncdeq/afo/AWI310035P20210331.pdf (Exhibit 1); DEQ, Benson Farm Permit No. AWI310039 (March 31, 2021), https://files.nc.gov/ncdeq/afo/AWI310039P20210331.pdf (Exhibit 2); DEQ, Kilpatrick Farm 1, 2, 4, & 5, & Merritt Farm Permit No. AWS92005 (March 31,2021), https://files.nc.gov/ncdeq/afo/AWS820005P20210331.pdf (Exhibit 3); and DEQ, Farm 2037 & 2038 (Goodson) Permit No. AWI820466 (March 31,2021), https://files.nc.gov/ncdeq/afo/AWI820466P20210331.pdf (Exhibit 4).

[2] DEQ, Draft Environmental Justice Report, 20 (Dec. 22, 2020), https://files.nc.gov/ncdeq/afo/Biogas-DWR-Draft-EJ-Report.pdf (hereinafter "DEQ EJ Report") (Exhibit 5) (explaining the findings of DEQ's environmental justice

The Permits authorize the Hog Operations to collect methane from hog waste lagoons for use as fuel ("biogas"), but they fail to address the longstanding, serious pollution problems of using open lagoons and sprayfields to store and dispose of hog waste—and in particular, they fail to address the *increases* in pollution that will result from the production of biogas at these operations under the new Permits.

Two local community groups, Environmental Justice Community Action Network and Cape Fear River Watch challenged these permits in the N.C. Office of Administrative Hearings alleging violations of state law. *See* Prehearing Statement, *Env't Justice Comm. Action Network & Cape Fear River Watch v. N.C. Dep't of Env't Quality – Div. Water Res & Murphy Brown, LLC*, Case Nos. 21 EHR 02068, 02069, 02070, 02071 (consolidated) (Exhibit 7). EJCAN and Cape Fear River Watch have not alleged violations of federal civil rights laws as part of the cases, which are currently pending.

DEQ's issuance of the Permits will put more harmful ammonia into the air nearby residents breathe, increasing fine particulate pollution associated with premature death and serious health problems. For example, a recent study by the National Academy of Sciences attributes an astounding 95 premature deaths in Sampson County and 83 premature deaths in Duplin County to the fine particulate pollution caused, in part, by ammonia emissions from hog operations every year.[3] The Permits will also increase the water pollution that results from ammonia settling in the surrounding area and more water-soluble pollutants being applied directly to crop fields.[4] These are unacceptable added harms for communities that have suffered from pollution and health problems from hog operations and other polluting industries for decades. DEQ's failure to address these added harms violates Title VI of the Civil Rights Act of 1964, 42 U.S.C. §§ 2000d to 2000d-7, as well as the Title VI implementing regulations of the U.S. Environmental Protection Agency ("EPA"), 40 C.F.R. Part 7.

Your office previously expressed "deep concern" about North Carolina's permitting program for industrial hog operations, which authorizes the storage of hog urine and feces in open cesspits and spraying of the waste on fields.[5] This harmful approach to waste management has been linked to severe environmental degradation and increased mortality and illness in nearby communities, and disproportionately burdens Black, Latinx, and Native American North Carolinians.[6] The Permits continue to rely on this primitive system, which EPA found may be

[6] *See, e.g.*, Julia Kravchenko et al., *Mortality and Health Outcomes in North Carolina Communities Located in Close Proximity to Hog Concentrated Animal Feeding Operations*, 79 N.C. MED. J. 278, 278 (2018), https://doi.org/10.18043/ncm.79.5.278 (finding higher mortality rates for people living near industrial hog operations) (Exhibit 11); *see also* Steve Wing, et al., *Environmental Injustice in North Carolina's Hog Industry*, 108

racially discriminatory and may provide "potential evidence of systemic concerns,"[7] and they make it worse by authorizing new waste systems that will increase the levels of harmful pollutants emitted from hog waste stored in open lagoons and sprayed into the environment.

The Permits issued by DEQ authorize not only the continued use of the discriminatory lagoon and sprayfield system, but also the use of anerobic digesters and uncovered "secondary" lagoons, which will exacerbate the underlying system's impacts on communities of color. DEQ's own Environmental Justice Report notes that this area has higher percentages of people of color as compared to the State, and in many cases, the county.[8] Yet drafting this report was merely a paper exercise; DEQ failed to address these impacts on nearby communities by including permit conditions that would protect nearby residents and the environment. For example, the Permits are ostensibly "non-discharge" permits that contain prohibitions against discharges of waste, yet they lack any groundwater and surface water monitoring to enforce these provisions. The Ninth Circuit Court of Appeals recently rejected this approach as arbitrary and capricious.[9]

The new waste treatment systems at the Hog Operations are nearly complete, and will shortly begin processing all of the hog waste at these operations through covered anaerobic digesters that change the chemical and biological processes to increase the amount of ammonium/ammonia and concentrate other harmful pollutants in the hog waste that remains after the biogas is removed; it is this waste that the Permits authorize to be dumped into polluting open cesspits and then sprayed on nearby fields.

Further adding to the urgency of this complaint is the passage of the North Carolina Farm Act in July 2021, N.C. Sess. L. 2021-78, which gives DEQ until July 2022 to develop a new general permit for biogas production at North Carolina's industrial hog operations.[10] The law creates a one-size-fits-all approach to permitting, limits community input and agency review of proposed projects, weakens long-standing siting restrictions, and removes tax incentives for the installation of cleaner waste management technology.[11] Further, it automatically approves coverage under the proposed general permit ninety days after DEQ receives applications for such coverage, all but guaranteeing a lack of adequate consideration of the concerns of neighboring residents or the local impacts on the environment or public health.[12] Smithfield Foods, the largest hog producer in North Carolina, estimates 90 percent of its industrial hog finishing operations will be producing biogas within the next decade.[13]

Env't Health Perspectives 225 (2000), https://www.ncbi.nlm.nih.gov/pmc/articles/PMC1637958/ (hereinafter Wing 2000 study) (documenting that hog operations are concentrated in areas with higher populations of people of color and low-wealth communities) (Exhibit 12).

[7] Dorka Letter, *supra* note 5, at 11 (explaining that EPA's External Civil Rights Compliance Office (ECRCO) "continues to be concerned about possible discriminatory impacts" from the lagoon and sprayfield system because the findings of its investigation "indicates that the [ ] adverse impacts described [in the investigation report] are being felt by large segments of the communities of color and are potential evidence of systemic concerns, not purely anecdotal claims").

[13] Press Release, *Smithfield Foods Announces Landmark Investment to Reduce Greenhouse Gas Emissions*, SMITHFIELD FOODS (Oct. 25, 2018), https://www.smithfieldfoods.com/press-room/2018-10-25-Smithfield-Foods-

As Reverend Jimmy Melvin of the Mt. Zion AME Zion Church in Sampson County recently explained, "[b]lanket permission will just add more to the backs of people like our parishioners, who have worshipped in our church for generations and also borne so much of the environmental burden of industrial agriculture."[14] Complainants request that EPA act quickly to protect communities of color living in eastern North Carolina.

The Duplin County NAACP and the North Carolina Poor People's Campaign request that the External Civil Rights Compliance Office ("ECRCO") enforce Title VI of the Civil Rights Act of 1964 and EPA's implementing regulations, and respond to this complaint with the full force of the law to protect communities of color who live and work near hog operations whose biogas production and animal waste management systems will unsafely dispose of waste, exacerbating the ongoing public health and pollution burden on these families unless DEQ changes its current permitting policy of ignoring these pollution problems and the disparate impacts they create.

I. COMPLAINANTS

The Duplin County NAACP is non-profit public interest organization with members in Duplin County, where two of the Hog Operations are located. The Duplin County NAACP was founded in 1946, and is a local branch of the nation's oldest and largest civil rights organization whose mission is to ensure the political, educational, social, and economic equality of rights of all persons and to eliminate racial hatred and discrimination. The Duplin County NAACP works to promote this mission by engaging in local issues across the state and in Duplin County. The NAACP has also long been involved in seeking environmental justice for low income communities and for people of color.

The North Carolina Poor People's Campaign is part of the national Poor People's Campaign, which was formed to confront the interlocking evils of systemic racism, poverty, and ecological devastation, among other issues. The Campaign aims to shift the moral narrative and impact policies at every level of government, and build lasting power for poor and impacted people. The North Carolina Poor People's Campaign is a network of compassionate, hardworking people from all walks of life from across North Carolina who are dedicated to advancing racial, social, and economic justice for their communities. The Poor People's Campaign Circles are groups that represent the different geographical regions of the state.

Announces-Landmark-Investment-to-Reduce-Greenhouse-Gas-Emissions (last visited Sept. 21, 2021). Three of the four Hog Operations are part of the first large-scale biogas project sponsored by Align RNG, a joint venture of Smithfield Foods and Dominion Energy. According to public statements, the project will involve capping hog waste lagoons at 19 industrial hog operations, laying approximately 30 miles of pipeline connecting the hog operations and a processing plant, and constructing a processing plant where the biogas will be collected, processed, and injected into the existing natural gas pipeline. DEQ is an agency of the State of North Carolina. N.C. Gen. Stat. § 143B-279.1. The North Carolina General Assembly charged the agency to protect the environment and human health. *Id.* at § 143B-279.2. DEQ has the authority to issue permits, including permits for animal feeding operations, to carry out this charge. *Id.* at § 143-215.1.

II. JURISDICTION

EPA has jurisdiction over a complaint under Title VI of the Civil Rights Act of 1964 if the complaint meets four requirements: (1) the complaint is in writing; (2) the complaint alleges discriminatory acts that, if true, violate EPA's Title VI regulations; (3) the complaint identifies a recipient of EPA funding that committed the alleged discriminatory act; and (4) the complaint is filed within 180 days of the alleged discriminatory act.[15]

This written complaint is timely filed and identifies violations by DEQ, a state government agency that receives EPA funding and is thus bound by Title VI of the Civil Rights Act of 1964.[16] At the time the Permits were issued, DEQ was a recipient of EPA assistance.[17] According to USASpending.gov, "the official source for spending data for the U.S. Government,"[18] EPA awarded DEQ $165,891,031 in fiscal year 2020 and $68,583,413 in fiscal year 2021.[19] DEQ is required to comply with Title VI and EPA's Title VI implementing regulations but failed to do so, resulting in disproportionate adverse impacts to individuals protected under Title VI.

III. FACTUAL BACKGROUND

A. Pollution from lagoons and sprayfields disproportionately affect communities of color in eastern North Carolina.

For decades, the swine industry has avoided properly managing animal waste to prevent pollution, and instead displaced harm onto communities of color.[20] As a result, North Carolinians

[20] *See* Wing 2000 Study, *supra* note 6, at 229-30 (finding that North Carolina's more than 2,000 industrial hog hog operations are "located disproportionately in communities with higher levels of poverty, higher proportions of nonwhite people, and higher dependence of wells for household water supply"); *see* Steve Wing & Jill Johnston, *Industrial Hog Operations in North Carolina Disproportionately Impact African-Americans, Hispanics and*

who live close to hog operations experience a lower life expectancy and higher likelihood of death from common illnesses than those who live further away.[21] Research has repeatedly shown that industrial hog operations are much more likely to be located near Black, Latinx, and Native American residents than White residents.[22]

These hog operations are concentrated in the Black Belt—the crescent-shaped swath of dark, fertile soils stretching from Virginia to Mississippi where large numbers of African Americans were enslaved on plantations before the Civil War.[23] Many formerly enslaved people stayed in the area after Emancipation and worked as farmers, on their own land or as sharecroppers or tenant farmers.[24] Some Black families live on land that has been passed down for generations.

In addition to Black residents, Native Americans have lived in eastern North Carolina since before European settlers began arriving in the 1600s. The Waccamaw Siouan and Lumbee tribes are located in eastern counties, as well as an Urban Indian Organization in Cumberland County.[25] The Coharie Tribe, one of North Carolina's eight recognized American Indian tribes,[26] is located in Sampson and Harnett counties, where approximately 80% of the tribe's 3,000 members reside within tribal communities around the Little Coharie River.[27]

There is also a large, growing Latinx population in this part of the State. Among all counties in North Carolina, Duplin and Sampson counties have the largest share of their population made up of Latinx residents.[28]

In 2013, hundreds of neighbors, most of whom are Black, filed private nuisance claims against Smithfield Foods, claiming that the company's use of the lagoon and sprayfield system

made living nearby unbearable.[29] Five juries heard these cases, and each jury sided with the plaintiffs and also awarded punitive damages, indicating that Smithfield willfully and wantonly disregarded these conditions that significantly diminished neighbors' quality of life.[30] One of these cases was appealed, and U.S. Court of Appeals for the Fourth Circuit affirmed the verdict as to liability for compensatory and punitive damages.[31] In a scathing concurrence, Judge J. Harvie Wilkinson described the "outrageous conditions" endemic in the use of "large uncovered cesspool[s]" that "bred horrible outcomes for pigs and human alike," including toxic gases, noxious fumes, respiratory problems, increased likelihood of asthma among children, and the presence of buzzards and flies.[32]

Shortly after these nuisance cases were filed, in 2014, the North Carolina Environmental Justice Network, the Rural Empowerment Association for Community Help, and Waterkeeper Alliance filed a Title VI complaint with this office against DEQ.[33] These complainants asserted that DEQ's issuance of the swine general permit, which covers the majority of industrial hog operations in North Carolina, violated Title VI because it authorized industrial hog operations to use "grossly inadequate and outdated systems of controlling animal waste . . . [that have] an unjustified disproportionate impact on the basis of race and national origin against African Americans, Latinos and Native Americans[.]"[34]

In 2017, after a months-long investigation, this office expressed "deep concern about the possibility that African Americans, Latinos, and Native Americans have been subjected to discrimination as the result of NC DEQ's operation of the Swine Waste General Permit program[.]"[35] Key findings included that:

- People experienced an increase in the number and severity of health effects, like asthma and other respiratory illnesses, nausea, and headaches, which residents reported were "compounded by the increase in industrial poultry operations, as well as the operation of landfills and waste disposal sites for hog sludge and carcasses."[36]

[29] *See* Barry Yeoman, *Here are the rural residents who sued the world's largest hog producer over waste and odors – and won*, FOOD & ENV'T REPORTING NETWORK (Dec. 20, 2019), https://thefern.org/2019/12/rural-north-carolinians-won-multimillion-dollar-judgments-against-the-worlds-largest-hog-producer-will-those-cases-now-be-overturned/. After these cases were filed, the North Carolina General Assembly adopted House Bill 467 in 2017 and Senate Bill 711 in 2018, which together significantly limited the ability for neighbors living nearby hog operations to sue for nuisance. Several community groups have challenged these legislative actions as violations of the North Carolina Constitution; this litigation is pending. *Rural Empowerment Ass'n for Comm. Help, et al. v. State of N. Carolina*, Docket 21-175 (N.C. Ct. of Appeals).

- The stench and fear of health impacts caused residents to feel a loss of community because young people leave and do not return, and people no longer gather together outdoors.[37]

- Community members were concerned that the drinking water, fish, and vegetables grown in home gardens were contaminated by pollution from the industrial hog operations. They also could no longer keep their windows open or dry clothes outdoors when nearby hog operations were spraying untreated waste on fields. People spent money on water, clothes dryers, air fresheners, pesticides, air conditioning, and food, to try to deal with the odor and avoid potentially contaminated food and water.[38]

The 2014 complaint resulted in a settlement with DEQ, which required, among other things, that DEQ enhance public participation, stakeholder engagement, and communication with community members impacted by DEQ permitting decisions.[39] DEQ also agreed to conduct environmental justice analyses and develop an environmental justice mapping tool to evaluate impacts of permitting decisions on community members.[40] That settlement does not address the increased pollution risks from biogas digester waste that DEQ has authorized with the Permits.

These problems found by EPA in 2017 persist today and are likely to get worse as a result of the Permits. Industry-sponsored biogas projects exacerbate this long-standing environmental injustice by increasing the risks of the polluting lagoon and sprayfield system without addressing the system's disproportionate impact on communities of color.[41]

B. Pollution and harm to human health from the industry's use of lagoons and sprayfields is well-documented and long standing.

Approximately 9 million hogs are housed at more than 2,000 industrial hog operations in the low-lying, flood-prone coastal plain of eastern North Carolina.[42] Duplin and Sampson counties produce more hogs and poultry than any other counties in the state[43] and more hogs

than any other counties in the nation.[44] Hogs produce an enormous amount of waste—billions of gallons of waste each year.[45]

Industrial hog operations in North Carolina use the harmful and primitive "lagoon and sprayfield" system to dispose of this waste. Untreated hog urine and feces are stored in giant open cesspits, known as lagoons. The chemical and biological processes that take place in these lagoons generate and release harmful pollutants such as ammonia and methane. Periodically the waste is pumped out of the pits and sprayed into the air and onto nearby fields. The spray often blows onto neighboring homes and passing cars.[46] Even when operators only spray as much waste as the crops can use, which is referred to as the agronomic rate, pollutants in the waste reach rivers and streams through leaching and runoff.[47] When waste is applied above the agronomic rates, excess nutrients also run off into surface waters and leach into groundwater.[48] Making matters worse, operators often pump down the liquid in lagoons ahead of major rainfall events to reduce the risk of lagoon overflows; often the land is oversaturated and the sprayed waste runs off the fields onto neighboring properties and streams during and after these heavy rain events.[49] The lagoon and sprayfield system causes significant pollution; this system

degrades rivers and streams,[50] contaminates groundwater,[51] poisons the air,[52] and detrimentally impacts quality of life for nearby families.[53]

Hog waste pollutes waterways in four primary ways: (1) runoff of pollutants from sprayfields; (2) leaching of pollutants into groundwater from lagoons and sprayfields; (3) atmospheric deposition of ammonia from barns, lagoons, and spraying into surface waters and land; and (4) spills from lagoons and flooding of sprayfields due to weather or other failures. The agronomic rate applies exclusively to nitrogen, allowing phosphorus and heavy metals to be applied at high concentrations without any consequences.[54] Numerous studies have shown that hog operations routinely apply more waste to fields than can be absorbed,[55] leading to excessive nitrogen and phosphorus in soils, groundwater, and surface water.[56] Eastern North Carolina's high water table and sandy soil composition make the region particularly vulnerable to pollutants leaching into groundwater.[57] Making matters worse, the pollutants then migrate through groundwater into nearby surface waters.[58] For decades, scientists have documented seepage of contaminants from hog waste lagoons into nearby surface and groundwater.[59] In the 1990s, researchers found the majority of lagoons studied in North Carolina leached pollutants, including

fecal bacteria, nitrogen, and phosphorus, into groundwater.[60] Many of those lagoons remain in operation today.

The threat of groundwater contamination is particularly serious for communities in eastern North Carolina where the vast majority of industrial swine operations are located, because these communities are heavily dependent on well water for drinking water.[61] Groundwater contamination from pathogens and nitrates present in swine waste can have devastating impacts on human health.[62] In 1995, the North Carolina Governor's Office initiated a water testing program for residents located near industrial animal operations; by 1998, 1595 wells in 57 counties had been tested, over 10 percent of which had nitrate contamination at or above the drinking water standard of 10 parts per million.[63] Duplin and Sampson Counties had higher percentages of contamination: nitrate levels greater than 9.5 parts per million were found in 22.5 percent of tested wells in Sampson County and in 11.7 percent of tested wells in Duplin County.[64] Other pollutants from lagoons and sprayfields, including phosphorus, fecal coliform, and heavy metals, have also been found in groundwater and surface waters near hog operations, often at levels that exceed drinking water standards.[65]

This year, the congregation of Mt. Zion AME Zion Church in Sampson County, which is surrounded by hog operations, was forced to spend more than $3,800 to dig a deeper well for the church after the County posted notices at the church that the water was unsafe to drink due to high levels of nitrates detected in the water.[66] As Rev. Melvin put it, "I participated in the public hearings to share my concern about the biogas facility and share my church's experiences with ground water issues. I also drove to Raleigh a little over a month ago to share my concerns in

person. It seems my concerns have fallen on deaf ears. . . . This is not only a water and environment issue. It is a humanity issue."[67]

Almost all of North Carolina's industrial hog operations, including the Hog Operations that received the Permits, are located in the flood prone, low-lying eastern coastal plain.[68] During rain events, which are becoming increasingly more severe and frequent,[69] hog waste lagoons are often damaged or flooded and sprayfields flood, releasing untreated waste into nearby rivers and streams.[70] For example, during Hurricane Florence in 2018, millions of gallons of hog waste spilled into rivers and streams throughout eastern North Carolina.[71]

Lagoons are also prone to leaking or overflowing on sunny days. The first major spill to capture the attention of policy-makers and the public occurred in 1995, when 25 million gallons of raw hog sewage spilled into the New River.[72] More recently in December 2020, a Jones County hog operation that had been cited twice for freeboard violations in the last year, spilled 1 million gallons of untreated hog waste into the Trent River after a lagoon breached.[73] In 2017 and again in 2019, the Waters Operation—one of the four Hog Operations DEQ permitted to produce biogas— spilled hog waste into a nearby stream due to equipment malfunctions.[74]

[74] See *infra* Section III(E).

This pollution causes terrible health effects for people living nearby, including serious, chronic illnesses and premature death. Earlier this year, the National Academy of Sciences published a study linking emissions from industrial hog operations to increased mortality in nearby communities.[75] Ammonia-derived particulate matter with a diameter of 2.5 microns or less, known as PM2.5, can penetrate deep into lungs and case serious cardiovascular and respiratory problems.[76] There is a well-established link between particulate matter and various adverse health outcomes including increased mortality rates.[77] This study found that the emissions from industrial hog operations are responsible for a combined total of 178 premature deaths in Sampson and Duplin Counties annually.[78]

In addition, researchers have documented excessive respiratory symptoms in neighbors of hog lagoons and increased levels of mood disorders, including anxiety, depression, and trouble sleeping.[79] Children living near industrial hog operations have an increased risk of asthma.[80] In 2018, researchers from Duke University found that in North Carolina communities near hog operations using the lagoon and sprayfield system, mortality rates are substantially higher from common diseases such as anemia, kidney disease, tuberculosis, and lower birth rates than residents who live further away from these operations.[81] The study also found higher rates of low birth weight and infant hospitalization among residents who live near industrial hog operations.[82] The presence of nitrate in wells used for drinking water endangers the health of infants, pregnant women, children, the elderly, and others with weakened immune systems.[83]

Hog operations' use of polluting waste management systems disrupts communities, curtails social and recreational opportunities, and likely contributes to a loss in generational wealth for people of color in particular.[84] In addition to economic, environmental, and health impacts, the lagoon and sprayfield system also has adverse social impacts, reducing quality of life for communities and making it difficult or impossible for people to enjoy time together

outdoors.[85] The waste management practices also bring conflict into communities. As EPA has found, people who complain about the odor and other negative aspects of the hog operation often are ignored or harassed.[86] They also are more likely to have fewer financial resources—"[t]he concentration and industrialization of agriculture are associated with economic and community decline locally and regionally[.]"[87] People living nearby these hog operations also experience a loss of community because of the odors, decreased quality of life, and pollution resulting from lagoons and sprayfields.[88]

C. Storing digester waste in open lagoons and spraying it on fields without cleaner technology is likely to increase harm to the community and the environment.

Under the new Permits issued by DEQ, the hog waste will be moved from confinement barns into covered anaerobic digesters, where the waste will break down faster and to a greater extent than in a conventional lagoon.[89] Processing waste in a covered lagoon and removing the biogas significantly alters the properties of the resulting waste. The process increases the concentration of ammonia/ammonium (forms of nitrogen)[90] and produces other forms of nitrogen, namely nitrate and nitrite, that are more likely to infiltrate groundwater and run off into surrounding waterways when land-applied.[91] Once the biogas is siphoned off, the remaining waste will be pumped to one or more open-air secondary lagoons. Due to the increased ammonia/ammonium concentration, the waste in the open secondary lagoon is likely to emit significantly more ammonia than a conventional open-air hog waste lagoon.[92]

---

AIR & WASTE MGMT. ASS., 1145, 1156 tbl. 4 (2008) (finding a 11.9% increase in ammonia emissions from an open secondary lagoon storing digester waste over an open lagoon storing conventional hog waste) (hereinafter Aneja 2008 Study) (Exhibit 41); *see also* Kupper et al., *Ammonia and greenhouse gas emissions from slurry storage—A Review*, 300 AGRICULTURE, ECOSYSTEMS, & ENV'T 1, 9 tbl. 10 (2020) (the one result showing emission decreasing was from a lab study where the waste was stored in sealed, heated containers) (Exhibit 42); *see also* Lowry A. Harper et al, *The Effect of Biofuel Production on*

In short, with the more-polluting digester waste being stored and disposed of using open lagoons and sprayfields under the waste system DEQ has authorized, any benefits from capturing emissions of methane and other gases through biogas production will come at the expense of not only ongoing but *increased* ammonia emissions, increased mobility of pollutants, and resulting air and water pollution. Furthermore, for all but one of the four Hog Operations, these new systems do not even reduce the amount of open lagoons susceptible to overflowing during rain events, and in fact add an additional waste-holding structure—the anaerobic digesters—which has potential to leach pollutants into groundwater.

Additional technologies that address water and air pollution—and that are compatible with biogas production—are available and practicable. Comments submitted to DEQ during the permitting process suggested additional technologies and called on DEQ to comply with its statutory obligation under N.C. Gen. Stat. § 143-215.1(b)(2) to require the practicable waste treatment and disposal alternative with the least adverse impact on the environment.[93] Yet the Permits do not require any additional treatment of this more harmful waste to reduce impacts to the environment and nearby communities.[94] As a result, these new biogas permits stand to worsen harm to the communities living near industrial hog operations in Duplin and Sampson counties, and in particular communities of color.

i. The digester process increases ammonia emissions.

Anaerobic digesters capture methane and other gases unlike conventional open-air hog waste lagoons which emit these gases directly into the atmosphere. However, the process of anaerobic digestion and removal of methane (a form of carbon) alters the composition of the remaining waste in the digester ("digester waste"). The digester waste contains more ammonia and ammonium, less carbon, and has a higher pH.[95] As a result, digester waste stored in open secondary lagoons and land-applied is likely to emit *more* ammonia into the atmosphere than conventional hog waste lagoons or fresh hog waste.[96] Increased ammonia emissions from an open lagoon storing digester waste has been documented in North Carolina and many other

---

Swine Farm Methane and Ammonia Emissions, 39 J. ENV'T QUAL. 62 (2010), https://pubmed.ncbi.nlm.nih.gov/21284295/ (finding a 46 percent increase in ammonia emissions from mesophilic biogas digester relative to control lagoons) (Exhibit 43).

[93] *See, e.g.*, Letter from Blakely Hildebrand and Maia Hutt, SELC, to Ramesh Ravella, DEQ (Jan. 29, 2021) (hereinafter Comment Letter) (Exhibit 44).

[94] DEQ admitted that "atmospheric loses from the lagoons" would occur, and relies on this statement to support its statement that land-applied digester waste will not contain a higher concentration of pollutants than waste from a conventional hog lagoon. *See* Public Meeting Report, *infra* note 122, at 18.

[95] *See* Jeffery Lorimor & John Sawyer, *Final Report: Swine USA Anaerobic Digester Performance Analysis*, NAT. RES. CONSERVATION SVC. – IOWA STATE UNIV. 3, 5 (2004) (Exhibit 45); Baines, *supra* note 90, at 116 (explaining that as ammonia (NH_3) increases as a portion of Ammoniacal nitrogen, pH also increases); Roger Nkoa, *Agricultural benefits and environmental risks of soil fertilization with anaerobic digestates: a review*, 24 AGRONOMY FOR SUSTAINABLE DEV. 473, 480 (2015), https://hal.archives-ouvertes.fr/hal-01234816/document (Exhibit 46).

[96] *See* Aneja 2008 Study, *supra* note 92, at 1155, 1156; Harper et. al, *supra* note 92; Kim Weaver et al, *Effects of Carbon and Nitrogen Emissions due to Swine Manure Removal for Biofuel Production*, J. ENV'T QUALITY, 1371, 1374 (2012) (Exhibit 47); T. Nyord et. al, *Ammonia Volatilization and crop yield following land application of solid-liquid separated, anaerobically digested, and soil injected animal slurry to winter wheat,* 160 J. AGRIC., ECOSYSTEMS, AND ENV'T, 75, 78 (2012) (Exhibit 48); Nkoa, *supra* note 95, at 480.

places.[97] When the digester waste effluent is applied to fields, the increased rate of ammonia emission is likely to continue.[98] This is especially the case in summer months and with the use of high pressure spray irrigation equipment at the Hog Operations.[99] For this reason "[d]igested slurry … has to be stored in covered slurry stores" and experts "strongly recommend to apply biogas slurry with low-emission techniques near or below the soil surface."[100] The permits issues by DEQ fail to require either of these necessary safeguards.

ii. Increased ammonia emissions harm air quality and water quality.

Increased ammonia emissions from secondary open-air lagoons and land application worsen air quality and water pollution. Ammonia travels through the air and deposits on land, contaminating soil, groundwater, and ultimately rivers and streams, and also deposits directly in waterways.[101] Atmospheric deposition of ammonia accounts for a significant portion of nitrogen impacts in North Carolina's coastal ecosystems, including the Albemarle and Pamlico Sounds.[102] Aerosolized ammonia can travel as far as 60 miles from its point of origin.[103] Ammonia emissions can contribute to eutrophication of waterways, and can reduce dissolved oxygen levels.[104]

(Exhibit 53); *see* Costanza, *supra* note 102, at 77; Burkholder 2007 Study, *supra* note 47, at 309 ("Inorganic N forms are added to the

When exposed to oxygen and deposited on soils, ammonia is converted to nitrate, which is highly soluble in water, which means water carries the nitrate with it as it moves through and over soil.[105] Sandy soils are prevalent in eastern North Carolina, including at the Hog Operations, and the water table is high, increasing the risk that nitrate moves into groundwater and eventually into nearby streams.[106] Nitrate is a form of nitrogen whose presence in drinking water has been linked to various health effects including blue baby syndrome.[107] In addition, this increased nitrate pollution can lead to algal blooms, affect aquatic life, and drive down dissolved oxygen levels in waterways, which in turns creates biochemical oxygen demand and results in degraded water quality that is unsafe and/or undesirable for recreation.[108]

Ammonia air pollution can cause adverse health impacts in humans and drives production of PM2.5, which is associated with respiratory issues in humans.[109] Furthermore, airborne ammonia deposited on land and various forms of nitrogen, including nitrate, in hog waste sprayed or land-applied on crop fields can pollute groundwater.[110]

In sum, the increased ammonia emissions as a result of the Permits are likely to further degrade groundwater, surface water, and air quality.

iii. The secondary lagoons are still at risk for flooding and failures

The installation of covered anaerobic digesters does not address the significant risk of pollution from industrial hog operations during major rain events, which are becoming more frequent and intense because of climate change. As noted above, the lagoon and sprayfield system is extremely vulnerable to flooding during major rain events. Uncovered secondary lagoons will continue to be vulnerable to inundation and structural failure, while sprayfields remain equally susceptible to flooding from major storm events. For example, the Goodson Operation in Sampson County is located partially within the FEMA flood hazard zone, with at least one sprayfield located in the floodplain.[111]

The permits issued by DEQ for all but one of the four Hog Operations do not even reduce the amount of open lagoons susceptible to overflowing during rain events, and in fact add an

---

atmosphere during spray practices, and both ammonia and phosphate can also adsorb to fine particles (dust) that can be airborne . . . [A] significant proportion of the total ammonium from uncovered swine effluent lagoons and effluent spraying . . . reenters surface waters as local precipitation or through dry fallout.").

[111] DEQ, Certificate of Coverage No. AWS820466, Farm 2037 and 2038 (Sept. 23, 2019), https://edocs.deq.nc.gov/WaterResources/DocView.aspx?id=1114491&dbid=0&repo=WaterResources.

additional waste-holding structure—the anaerobic digesters—which has potential to leach pollutants into groundwater. Moreover, the secondary lagoons and sprayfields will store more concentrated waste that is more likely to contaminate groundwater and move with runoff, increasing the risk of pollution, particularly during major rain events.

As illustrated below, the Hog Operations at issue here are all located in the lower Cape Fear River Basin, close to tributaries of the Cape Fear River. The Goodson Operation is located on Six Runs Creek. The Kilpatrick and Waters Operations are located on Stewarts Creek, which drains into Six Runs Creek. The Waters Operation is also near Murpheys Creek, which drains into Rockfish Creek. The Benson Farm is located near Goshen Swamp and Nahunga Creek. In 2015, the United States Geological Survey sampled at multiple sites along Six Runs Creek and a site at Nahunga Creek,[112] and based on the levels of nitrates and other pollutants, concluded that there were "[swine] waste manure influences" on water quality at each site.[113] The proximity of these waterways to the Hog Operations increases the chances of flooding, and thus pollution into waterways. DEQ's recent sampling on Murpheys Creek downstream of the Waters Operation showed elevated levels of nitrate, among other pollutants.[114]

D. DEQ has failed to protect people of color and the environment from hog waste pollution.

Despite being on notice of these environmental injustices for many years and despite the settlement reached after the 2014 Title VI complaint referenced above, DEQ has done little to actually prevent or reduce disproportionate harms caused by industrial hog operations. Pollution from the lagoon and sprayfield system persists today, and DEQ's current permitting approach to biogas projects is only making it worse.

Despite having agreed to do so, DEQ has not initiated rulemaking to codify a Violation Points System, which is required by state law.[115] The Violation Points System would hold repeat violators accountable for continued non-compliance with their permit and protect the

[115] *See* Settlement, *supra* note 39, at 5; *see also* N.C. Gen. Stat 143-215.6E.

environment and the surrounding communities. In the meantime, DEQ enforcement efforts have fallen short and fail to protect communities and the environment. When DEQ identifies violations or deficiencies, the agency rarely initiates enforcement actions. For instance, in 2020, DEQ found 224 deficiencies and violations during annual inspections.[116] Yet DEQ only initiated 29 enforcement actions against violators.[117]

More recently, DEQ has enabled the hog industry's push for biogas.[118] On March 31, 2021, DEQ issued the Permits. The Permits are a continuation of this history of systemic discrimination. Despite strong pushback and legal challenges from community members and environmental groups,[119] reams of research documenting the harms of the system,[120] and reduced capacity for proper enforcement, DEQ continues to authorize the industry to use the lagoon and sprayfield system at existing operations at the expense of community health and the environment.[121]

E. The Hog Operations have repeatedly violated their permits.

The Hog Operations have histories of non-compliance with their permits, increasing the risks of pollution. In fact, during the site visit before the Permits were issued, DEQ staff noticed several compliance issues, including high freeboard levels and mismanagement of pollutant-laden sludge.[122] Nevertheless, on March 31, 2021 DEQ issued the Goodson, Waters, and Benson operations were new individual permits to install new anaerobic digesters, produce biogas, and dispose of digester waste in secondary open lagoons and crop fields, and the Kilpatrick Operation was issued a new certificate of coverage under the state general permit to convert an existing lagoon into a covered anaerobic digester, produce biogas, and dispose of digester waste in secondary open lagoons and crop fields.[123]

In recent years, the Goodson Operation has struggled to comply with requirements meant to prevent waste from contaminating nearby rivers and streams.[124] For example, in March 2019

[123] See Permits for the Hog Operations, *supra* note 1.

[124] *See* Compliance History for Goodson Farm (Farm 2037 & 2038) (Jan. 2019-Mar. 2021) (Exhibit 62).

an inspection report indicated an overflow of hog waste at the facility. A December 2019 Plan of Action for sludge management shows the facility violated the sludge requirements for two of the lagoons on-site and was required to remove nearly five million gallons of pollutant-laden sludge that had accumulated at the facility in order to come back into compliance. And on at least four occasions in the past year alone, the facility failed to maintain sufficient storage capacity in its lagoons to avoid waste overflowing during heavy rainfall.

Like the Goodson Operation, the Waters Operation has also repeatedly failed to maintain sufficient room in its lagoons to prevent a spill of untreated hog waste during a heavy rainfall.[125] In 2017, a pipe at the operation broke, leading to the spill of 900 gallons of hog waste into an unnamed tributary of Stewarts Creek. On May 20, 2019, a pipe at one of the lagoons cracked, causing 13,200 gallons of raw hog feces and urine to gush out of the lagoon at a rate of 10 gallons per minute, some of which spilled down a ditch and into a nearby creek. The Waters Operation also kept too much sludge in all of its lagoons, violating its sludge level requirements.

In an April 2020 inspection report, DEQ noted the Benson Operation facility was "out of compliance with permit conditions related to sludge" because sludge accumulation in the lagoons at the facility exceeded safe levels.[126]

The Kilpatrick Operation is located very close to the 100-year floodplain. It too has a history of non-compliance with its permit requirements. In 2019, the facility built up more pollutant-laden sludge in its lagoons than was allowed, and it was required to remove more than 1.3 million gallons to come back into compliance.[127]

F. DEQ's Permitting Process Did Not Prevent Disparate Impacts.

i. The Permitting Process

On December 23, 2019, Murphy-Brown submitted four applications for permit modification for the Hog Operations.[128] On December 22, 2020, DEQ issued draft permits for each of the Hog Operations and a notice of a public hearing and a public comment period. DEQ solicited comments from the public between December 23, 2020 and January 29, 2021. On March 31, 2021, DEQ issued individual waste management permits to the Waters Operation, Benson Operation, and Goodson Operation and a modified certificate of coverage under the swine general permit for Kilpatrick Operation.[129]

[125] Compliance History for Waters Operation (Mar. 2018-Mar. 2021) (Exhibit 63).

[129] *Swine Biogas Processing Permitting Actions and Information*, N.C. DEP'T OF ENV'T QUALITY, https://deq.nc.gov/swinebiogas.

A virtual public meeting was held on January 26, 2021, through the WebEx online platform, and many people spoke out in opposition to issuance of the draft water permits.[130] Community members raised concerns about their personal health, the safety of their drinking water, noxious odors, and the wellbeing of their local economies, and asked DEQ not to issue the permits without considering the cumulative impacts of the many polluting industries in Sampson and Duplin counties.[131] One community member stated that "Sampson County is being turned into the county of waste and we really need to consider if we want to add to the waste issues that we are already dealing with . . . most of these neighborhoods are Black and Brown and we are being impacted the most."[132] Another community member demanded to know why DEQ wasn't protecting her community by requiring monitoring in the Permits.[133] Yet another community member implored DEQ to "listen to the concerns of the most impacted communities affected by the proposed [biogas] project and take the steps necessary to protect the health of these vulnerable communities."[134] Community members also requested that DEQ require Murphy-Brown to install cleaner technology that would address many of the adverse environmental and public health effects caused by covering a hog waste lagoon. Community and environmental groups submitted written comments opposing issuance of the draft permits, including comments that urged DEQ to evaluate and address the increased pollution risks from the Hog Operations and the disproportionate impacts of these permits on communities of color.[135]

ii. DEQ's own environmental justice report shows disproportionate impact on Black and Latinx people living near the Hog Operations

DEQ's own environmental justice report shows that the communities around the Hog Operations have disproportionately higher Black, Latinx, and low-wealth populations as compared to the rest of the state.[136] DEQ used EJSCREEN to report the demographics of communities within one mile of each of the Hog Operations.

As illustrated in Exhibit 6 f the people living within one mile of the Waters Operation 76 percent are people of color; within one mile of the Benson Operation 55 percent are people of color; within one mile of the Goodson Operation, 54 percent are people of color; and within one mile of the Kilpatrick Operation, 58 percent are people of color. The report also identifies two churches—Mount Pleasant Baptist Church and Six Runs Baptist Church—and *209 households*

within a one-mile radius of the four hog operations.[137] These congregations and households, which are predominantly made up of people of color and already bear the burden of the hog industry's pollution, as well as poultry operations and other polluting industries, would face additional environmental and health impacts if the permits are issued as drafted. Yet, the report did not include any recommendations or requirements for mitigating impacts to these communities.

IV. LEGAL VIOLATIONS

A. Legal Background.

i. Title VI of the Civil Rights Act of 1964 & EPA's Implementing Regulations

Title VI of the Civil Rights Act of 1964 prohibits recipients of federal funds from discriminating against individuals on the basis of race, color, or national origin, and provides that "[n]o person in the United States shall, on the ground of race, color, or national origin, be excluded from participation in, be denied the benefits of, or be subjected to discrimination under any program or activity receiving Federal financial assistance."[138] Title VI applies to all programs and activities receiving federal financial assistance.[139]

In 1973, EPA adopted nondiscrimination regulations implementing the purposes of Title VI. EPA regulations require state permitting agencies to minimize the "environmental impacts to local communities and ensur[e] that their practices and policies are implemented in a nondiscriminatory manner."[140]

In sum, federal civil rights laws and EPA regulations prohibit a recipient of federal funds from using criteria or methods of administering a program or activity which have the effect of subjecting individuals to discrimination.[141] Additionally, "Title VI imposes on states an affirmative obligation to include consideration of Title VI criteria in permitting decisions."[142] Therefore, DEQ—as a recipient of federal funds—is required to administer its permitting regime in a manner that does not have the effect of subjecting individuals to discrimination.

ii. North Carolina State Laws

The North Carolina General Assembly specifically "provid[ed] for the conservation of [the State's] water and air resources" and "achiev[ing] and [] maintain[ing] for the citizens of the State a total environment of superior quality,"[143] and authorized DEQ to deny a permit or attach

a condition to a permit when DEQ "finds such denial or such conditions are necessary to effectuate the purposes of this Article."[144] The General Assembly requires anyone seeking to carry out any activity that impacts the waters of the State, including construction or operation of an animal waste management system, to obtain and comply with a state permit.[145] DEQ's Division of Water Resources ("DWR") has the authority to grant, modify, or revoke any permit as necessary to effectuate the State's policies.[146]

B. Legal Violation.

i. The Permits issued by DEQ disparately impact Black and Latinx families in Duplin and Sampson Counties by increasing the risks of hog waste pollution.

DEQ's Permits authorize waste treatment systems that will put more harmful ammonia into the air that nearby residents breathe—an unacceptable added harm for communities that have suffered health problems from hog operations for decades. In addition, the ammonia emissions and other changes to the hog waste from biogas production will exacerbate pollution to groundwater, rivers, and streams nearby the Hog Operations, potentially contaminating drinking water for residents and causing algal blooms and fish kills.[147] The Permits also allow Murphy Brown to continue to dispose of waste using the harmful lagoon and sprayfield waste management system, about which EPA itself has expressed "deep concern."[148] These harms will be disproportionately borne by Black and Latinx neighbors of the Hog Operationsin violation of Title VI.

The Hog Operations at issue here are all located in parts of Duplin and Sampson Counties that are already overburdened by industrial pollution that has compromised surface water and groundwater quality in the Cape Fear River Basin and harmed the health and well-being of local, predominantly Latinx and Black communities.[149]

ii. DEQ's Failure to Prevent Disproportionate Adverse Impacts on Communities of Color Is Not Justified.

Many people, including impacted community members, submitted comments to DEQ during the public comment period for the Permits. As noted above, several themes emerged from these comments: concern about the Permits' risk to drinking water, concern about the Permits' impact on air quality, concern about the Permits' pollution of nearby waterways, and concern that these risks, as well as other negative impacts, would be disproportionately shouldered by predominately people of color already suffering under a legacy of industrial pollution facilitated by DEQ.

---

[144] *Id.* § 143-215.1(b)(1).
[145] *Id.* § 143-215.1(a)(12).
[146] *Id.* §§ 143-211(c) & 143-215.1(b). The General Assembly granted the Environmental Management Commission certain powers as to these permits, which the Commission delegated to the DEQ's Division of Water Resources. *Id.* § 143-211(c).
[147] *See supra* Section III(A)-(C).
[148] Dorka Letter, *supra* note 5, at 1, 6.
[149] *See supra* Section III.

As EPA Title VI regulations provide, "[i]n administering a program or activity receiving Federal financial assistance in which the recipient has previously discriminated on the basis of race, color, sex, or national origin, the recipient shall *take affirmative action* to provide remedies to those who have been injured by the discrimination."[150] Yet in the "Environmental Justice" response section of its public meeting report, DEQ cited no information on environmental or public health impacts, nor did it point to any substantive protections included in the Permits to address those impacts. Instead, DEQ stated only that it gave "meaningful consideration of Environmental Justice issues," and cited to the public notice and public hearing on the Permits as sufficient to resolve any environmental justice concerns.[151] This does not constitute DEQ taking action to resolve disparate impacts and is not sufficient.

Although it is true that DEQ drafted an environmental justice report as part of the permitting process, this report simply evaluated the demographics and socioeconomics of the project area. DEQ did nothing to reduce the disproportionate adverse impacts of the Permits on the Black and Latinx communities in Duplin and Sampson County as Title VI requires. The report itself is devoid of any actual analysis of these impacts, much less any recommendations for reducing these impacts.[152]

If DEQ could justify these environmental harms and other harms, it would need to "offer evidence that its policy or decision in question is demonstrably related to a significant, legitimate goal related to its mission."[153] But to date, DEQ has not put forward *any* justification for failing to consider disproportionate adverse impacts to communities of color, in the environmental justice report, public meeting report, or elsewhere. Nor could it, given that DEQ's Division of Water Resources' mission is "to protect, enhance, and manage North Carolina's surface water and groundwater resources for the health and welfare of the citizens of North Carolina and the economic well-being of the state."[154]

When considering whether a disparate impact on a particular community is justified, EPA guidance instructs DEQ to consider whether any purported benefits would be "delivered directly to the affected population," keeping in mind "the views of the affected community" about

---

[150] 40 C.F.R. § 7.35(a)(7) (emphasis added). Here, DEQ's permitting practices have had a disparate effect on people of color. *See, e.g.,* Dorka Letter, *supra* note 5, 1, 5-6; *see also* Complaint, *supra* note 33 (alleging discriminatory effect of DEQ's permitting of lagoons and sprayfield systems on people of color in eastern North Carolina). *See also* § 7.35(b) ("A recipient shall not use criteria or methods of administering its program or activity which have the effect of subjecting individuals to discrimination because of their race, color, national origin, or sex, or have the effect of defeating or substantially impairing accomplishment of the objectives of the program or activity with respect to individuals of a particular race, color, national origin, or sex.").

[151] *See* Public Meeting Report, *supra* note 122, at 17; *see also id.* at 13 (referencing non-specific "necessary monitoring requirements" as addressing commenters' concerns).

IXV, Sect. 5 ("It shall be the policy of this State to conserve and protect its lands and waters for the benefit of all its citizenry.").

whether the benefits justify the disparate impacts.[155] The community made its voice very clear, as the comments given indicate: it did not think the Permit benefited them, and thought it would actually harm them—socially, economically, and environmentally.[156]

DEQ is fully capable of ensuring that its permitting program fulfils its primary purpose while also avoiding discriminatory effects. Its decision to forgo such analysis here, despite comments and evidence suggesting that the decision to issue the Permits would cause disproportionate adverse impacts to Black and Latinx communities, violates Title VI's requirement to administer programs in a non-discriminatory manner.

iii. Less discriminatory alternatives to the Permits exist and are within DEQ's authority to require.

DEQ has the authority, indeed the obligation, to permit biogas projects in a way that protects nearby communities and the environment.[157]

Researchers and businesses have developed technologies and practices that significantly reduce the environmental impacts associated with managing hog waste, and industrial hog operations—including Murphy-Brown's parent company, Smithfield—have implemented such technologies elsewhere. These cleaner technologies include, for example:

- separating solids and liquids, which removes solid waste so it can be sold as fertilizers or soil amendments and minimizes sludge accumulation;
- nitrification-denitrification systems to eliminate nitrogen and nitrate, as well as reducing ammonia air pollution, from digester waste;
- alkaline treatment to address phosphorus and pathogens in digester waste; and
- injection or hose drag irrigation systems to apply waste directly to the soil, which reduces pollutant runoff.[158]

These technologies and practices have been successfully implemented, often in combination, on other hog operations in North Carolina and elsewhere and have significantly reduced the environmental impacts associated with hog waste management, and thus the impact

---

[155] Civil Rights Compliance Toolkit, *supra* note 153, at 15.

[156] *See, e.g.,* Public Meeting Report, *supra* note 122, at 12-13 (documenting comments from community members expressing concerns about public health, reduced property values, and the cumulative impacts of polluting industries, including poultry and hog operations, in the vicinity of the Hog Operations); *see also* Comment Letter, *supra* note 93.

[157] In addition to DEQ's obligations under federal civil rights and environmental laws, DEQ is also bound by state laws ensuring protection of the environment and public health. *See* N.C. Gen. Stat. § 143-215.1(b)(1) (providing that DEQ "prevent . . . any significant increase in pollution of the waters of the State"); *id*. § 143-211 ("It is the public policy of the State to maintain, protect, and enhance water quality within North Carolina."); *see also* 15A N.C. Admin. Code 2T.0108(c) (providing DEQ with the authority to "require monitoring and reporting requirements, including of groundwater, surface water or wetlands, waste, wastewater, residuals, soil, treatment processes, lagoon or storage ponds, and plant tissue, if necessary to determine the source, quantity, and quality of the waste and its effect upon the surface water, ground waters, or wetlands.").

[158] *See generally* Comment Letter, *supra* note 93, at 23-27; *see also* Garry Grabow, Overview of Different Lagoon Effluent Application Methods on Odor and Ammonia Emissions (2007) https://projects.ncsu.edu/project/swine_extension/ncporkconf/2007/generalsessions/grabow.pdf.

on communities living nearby.[159] These solutions are commercially available[160] and are compatible with the use of covered digesters to produce biogas. Community and environmental groups provided DEQ information about these and other alternatives during the permitting process.[161] Yet DEQ failed to include any additional treatment technology or other protective practices as part of the Permits.

DEQ also failed to include surface water monitoring or groundwater monitoring to confirm a basic assumption underlying the Permits—that the waste generated at the Hog Operations will not reach waters of the State or otherwise pollute the environment. Instead, DEQ ignored decades of research documenting pollution and public health harms from industrial hog operations utilizing the lagoon and sprayfield waste management system, including data from the agency itself.[162] Earlier this month, the Ninth Circuit Court of Appeals roundly rejected as arbitrary and capricious this approach of blindly assuming that non-discharge facilities do not affect water quality. *See Food & Water Watch v. U.S. Environmental Protection Agency*, No. 20-71554 (9th Cir. Sept. 16, 2021). The court stated, "[w]ithout a requirement to monitor runoff . . . there is no way to ensure that a [hog operation] is complying with the [p]ermit's . . . non-discharge requirement for land-application areas." *Id.* at 24-25. DEQ's permits contain exactly this fatal flaw.

DEQ also failed to add more protective freeboard or sludge management conditions to reflect the changing nature of the waste and the increased risk of water and air pollution, and did not require any operations to update their waste utilization plans or animal waste management plans before spraying of digester waste begins.

V. RELIEF REQUESTED

As detailed above, DEQ issued permits for biogas waste management systems that fail to protect the health and environment of families living near the Hog Operations, and in fact may make pollution and the risk of health harms even worse. And DEQ is preparing to issue a biogas general permit that will continue this same defective approach on an even greater scale.

These harms disproportionately affect Black and Latinx people living near the Hog Operations, and it is these communities who will suffer most if pollution from the Hog Operations worsens, as is expected with the Permits. Decades of research—including research reviewed by this office—demonstrate how the lagoon and sprayfield waste management system authorized by the Permits pollute rivers, streams, and air quality throughout eastern North Carolina. Despite this, and despite evidence indicating the increased risk of pollution and adverse health impacts to nearby residents from the increases to harmful hog waste pollutants resulting from biogas production, DEQ issued the Permits without addressing these harms. This is unacceptable and a violation of federal law.

Complainants request that ECRCO conduct an investigation to determine whether DEQ violated Title VI and EPA regulations in issuing the Permits with inadequate protections for the water quality and health of people living nearby, a disproportionate share of whom are Black and Latinx.

In addition, DEQ must change its current policy of refusing to consider ongoing and increasing water quality, air quality, and health impacts caused by the hog industry's polluting waste management systems. With regard to the Permits at issue in this complaint and future permits for biogas production, DEQ must identify, avoid, and if necessary mitigate any discriminatory effects caused by its permitting decisions. DEQ's policies and practices lead to disparate adverse impacts, and EPA should counsel DEQ on how to develop a permit decision-making policy that is fair, equitable, and Title VI-compliant going forward, as well as on how to administer that policy in a non-discriminatory manner.

VI. CONCLUSION

For all of the reasons outlined above, Complainants request that EPA accept this compliant for investigation, and upon a finding of disparate impact, bring DEQ into compliance with Title VI of the Civil Rights Act of 1964 and EPA's implementing regulations.

Thank you for your consideration of this matter. Should you have any questions or wish to discuss this matter further, please contact me at bhildebrand@selcnc.org or 919-967-1450.

Sincerely,

Re: Supplement to Complaint Number 05RNO-21-R4 Regarding the North Carolina Department of Environmental Quality's Issuance of Swine Farm Digester General Permit

Dear Administrator Regan and Acting Director Hoang:

On behalf of the Duplin County Branch of the North Carolina Conference of the National Association for the Advancement of Colored People ("Duplin County NAACP") and the North Carolina Poor People's Campaign (together, "Complainants"), the Southern Environmental Law Center submits this supplement to complaint number 05RNO-21-R4 ("2021 complaint"). The 2021 complaint alleges that the North Carolina Department of Environmental Quality ("DEQ") violated the U.S. Environmental Protection Agency's ("EPA") implementing regulations under Title VI of the Civil Rights Act of 1964, 42 U.S.C. §§ 2000d, *et seq*. ("Title VI"), when it issued four individual water quality permits authorizing digester systems at industrial hog operations in

Duplin and Sampson Counties in March 2021.[1] In issuing the 2022 Swine Farm Digester System General Permit ("Digester General Permit"),[2] DEQ again—and in the same ways—failed to comply with EPA's implementing regulations under Title VI.[3] Specifically, DEQ failed to conduct a comprehensive cumulative impacts analysis as part of the permitting process and failed to include necessary protections in the Digester General Permit that would mitigate air and water pollution at hog operations in eastern North Carolina. As a result of these failures, DEQ's decision to issue the Digester General Permit is likely to have a discriminatory impact on Black, Latino, and Native American families in eastern North Carolina.[4] The Digester General Permit suffers from the same deficiencies, and contains nearly identical terms, as the four individual permits that are the subject of the 2021 complaint and investigation. Like the four individual permits, a disproportionate share of the harms from operations covered by the Digester General Permit will be borne by communities of color. Unlike the four individual permits, however, more than 2,000 industrial hog operations in North Carolina could apply for coverage under the Digester General Permit.[5]

Notably, three of the four permits that were the subject of the 2021 complaint have since been rescinded, and those three facilities are now covered under the Digester General Permit.[6]

Complainants made OECRC aware of the then-forthcoming Digester General Permit in the 2021 complaint and in subsequent verbal and written communications with OECRC.[7] In the 2021 complaint, Complainants stated that "adding to the urgency of this complaint is the passage of the North Carolina Farm Act in July 2021, N.C. Sess. L. 2021-78, which gives DEQ until July 2022 to develop a new general permit for biogas production at North Carolina's industrial

[7] 2021 Complaint, *supra* note 1, at 3.

hog operations."[8] To emphasize the urgency of resolving this complaint, Complainants also cited to a provision of the 2021 Farm Act that automatically approves coverage under the Digester General Permit ninety days after DEQ receives a complete application.[9] Moreover, Complainants expressed concerns about the forthcoming Digester General Permit to OECRC repeatedly throughout the permitting process.[10] Complainants urged OECRC to move quickly in resolving the 2021 complaint and bringing DEQ into compliance with its obligations under Title VI, thereby influencing the terms and conditions within the Digester General Permit. Complainants also kept OECRC up to date about the Digester General Permit process, including sharing Complainants' written comments with the Office and alerting the Office when the Digester General Permit was issued on June 30, 2022.[11] Notably, OECRC tolled the investigation into the 2021 complaint on the same day, indicating that, after months of no response, DEQ signaled its willingness to participate in facilitated discussions to reach an informal resolution to the 2021 complaint.[12]

I. Issuance of the Digester General Permit

In July 2021, the North Carolina General Assembly passed the 2021 Farm Bill, which instructed DEQ to create a general permit for farm digester systems by July 1, 2022.[13] On February 1, 2022, DEQ issued a draft Digester General Permit.[14] On May 2, 2022, Complainants submitted written comments on the draft Digester General Permit, raising several concerns, including that the Digester General Permit as drafted violated Title VI and EPA's regulations.[15]

[15] *See* Comments on Draft Digester General Permit, *supra* note 11, at 52 – 57.

DEQ's Digester General Permit allows hog operations that are currently covered by the swine waste management system general permit to construct and operate animal waste management systems that include digester systems that produce biogas. The terms of the four individual permits are largely repeated in the Digester General Permit. The Digester General Permit allows hog operations to dig new lagoons, operate existing lagoons that lack a synthetic liner, and operate near impaired waterways. It does not require monitoring for ammonia or that secondary lagoons, which store digester waste, be covered or lined. It further allows digester waste, after being stored in an open-air secondary lagoon, to be sprayed on nearby fields. Moreover, the analysis included in DEQ's Environmental Justice Report showing the likelihood of disparate impacts on communities of color had no effect on DEQ's permitting decision; DEQ failed to include additional safeguards or application requirements for hog operations that will disproportionately harm communities protected by Title VI.

On July 28, 2022, the Environmental Justice Community Action Network and Cape Fear River Watch filed a petition for a contested case hearing challenging DEQ's issuance of the Digester General Permit.[16] The community groups claimed that, in issuing the permit, DEQ failed to consider the "practicable waste treatment and disposal alternative with the least adverse impact on the environment," as required by state water pollution control statute for "[a]ll permit decisions."[17] Murphy-Brown, LLC, a subsidiary of Smithfield Foods, Inc., intervened in that action.[18] Both DEQ and Murphy-Brown have argued that the state law requiring cleaner, practicable waste management technology does not apply to hog operations covered under the Digester General Permit. A decision in this case is expected in early 2023.

The Digester General Permit suffers from the same deficiencies as the individual permits. However, because a general permit, by its nature, covers more operations, the effects of the Digester General Permit will be felt in Black, Latino, and Native American communities across eastern North Carolina.

II. The Digester General Permit Authorizes the Same Polluting System as the Individual Permits

Many of the concerns raised in Complainants' 2021 complaint are present in the Digester General Permit. Like the individual permits, the Digester General Permit issued by DEQ authorizes use of the cesspit and sprayfield system. OECRC has previously expressed "deep concern" about North Carolina's permitting programs for industrial hog operations, which

[16] *Env't Just. Cmty. Action Network et. al v. N.C. Dep't of Env't Quality*, Case No. 22 EHR 02881, Petition for a Contested Case Hearing [hereinafter *EJCAN v. DEQ II*] (Exhibit 9). The parties had a hearing on motions for summary judgment on December 13, 2022.
[17] *See* N.C. Gen. Stat. 143-215.1(b)(2) ("All permit decisions shall require that the practicable waste treatment and disposal alternative with the least adverse impact on the environment be utilized.").
[18] *See EJCAN v. DEQ II*, Order Allowing Intervention (Sept. 19, 2022).

authorizes the storage of hog urine and feces in open cesspits and spraying of the waste on fields.[19] The Digester General Permit further entrenches use of the system by not only allowing operations with existing lagoons to install digesters and store digester waste in those existing lagoons, but also by permitting operations to dig new lagoons for digester systems.[20] Moreover, the permit includes no limits on venting or flaring methane and other harmful gases from digesters. As a result, communities living nearby these hog operations are likely to experience decreased air quality, contaminated drinking water, and more polluted water ways due to increasing ammonia emissions from the open-air secondary lagoons, increased methane production, and more harmful land-applied waste.[21]

Three of the four operations that received individual digester permits last year are now covered under the Digester General Permit; the fourth facility is likely having a significant effect on air quality and neighbors because the facility is not utilizing the methane and other gasses it is harvesting.[22] Both DEQ and Murphy-Brown, which owns all four of the individual operations, have argued in the past that coverage under the Digester General Permit would preclude any challenges to the individual permits.[23] But the facts remain the same: DEQ's permitting of digesters, whether under individual permits or a Digester General Permit, has had and is likely to have a disproportionate impact on communities of color.

III. More Facilities Will be Permitted Under the Digester General Permit

The Digester General Permit authorizes widespread construction and operation of digester systems with less permitting oversight. The Digester General Permit is open to any hog operation that is currently covered by the swine animal waste management general permit.[24] Currently, more than 2,000 hog operations are covered by the swine animal waste management general permit,[25] and the Digester General Permit does very little to prohibit, limit, or

particularize permit conditions for any of those operations. In fact, by its very design, the permit will more quickly approve permits for digester systems.[26] Industry has long stated its intentions to install digester systems at hog operations across the state.[27] While it is unknown exactly how many of these operations will apply for coverage under the Digester General Permit, the impacts and harms from these operations are likely to be felt disproportionately by the Black, Latino and Native American communities that more commonly live near industrial hog operations.[28]

IV. The Digester General Permit Will Disproportionately Harm Black, Latino and Native American Communities

A. The Digester General Permit Will Harm Communities in Eastern North Carolina

Like the individual permits, industrial hog operations permitted under the Digester General Permit will produce dangerous new waste streams that will harm people living nearby. Notwithstanding the existence of more environmentally protective pollution control technology, these operations will be authorized to dig new hog waste lagoons or cap existing unlined ones, install digester systems, store digester waste in open-air potentially unlined lagoons, and spray the ammonia-rich digester waste on fields across eastern North Carolina. Since Complainants filed their complaint last September, the harms authorized by North Carolina's issuance of the individual permits and the general permit have become even more evident.

As stated in Complainants' 2021 complaint to OECRC, digester systems exacerbate pollution and negatively impact human health. Several studies have shown that digester waste emits substantially more ammonia than hog waste from conventional lagoons. A study co-authored by North Carolina State University's Dr. Viney Aneja found that digester waste stored in uncovered secondary lagoons emits more ammonia per-hog than conventional hog waste in a lagoon.[29] Since Complainants' submission of their 2021 complaint, Dr. Aneja has further distilled the results from that study and isolated the source of the increase in ammonia emissions. He found that emissions from the open lagoon portion of the hog operation specifically increased by 66 percent relative to conventional lagoons.[30]

AIR & WASTE MGMT. 1145, 1152–55 (2008) (showing higher ammonia emissions from swine operation that utilized open hog lagoon).

[30] Viney P. Aneja, Ammonia Emissions from North Carolina Hog Operations' Animal Waste Management Systems to Produce Biogas, 1, 4 (Jan. 20, 2022) (Exhibit 13).

The removal of carbon from a digester makes the remaining nitrogen and phosphorus in the digester waste more soluble[31] and decreases dry matter in the waste[32] both of which can increase the ability of pollutants to infiltrate soil and contaminate groundwater. As a result, a leak or overflow from a lagoon storing digester waste can be even more devastating for the environment than a leak or overflow from a conventional lagoon.

The heightened risk of water pollution persists when, after being stored in the secondary lagoons, the digester waste is sprayed on nearby fields. When the waste is sprayed from high pressure hoses—the most common land-application method used on hog operations in North Carolina—more ammonia volatilizes and enters the atmosphere, where it compromises local air quality, drives particulate matter formation, and ultimately deposits in nearby waterways as nitrogen or nitrate.[33] Once the digester waste reaches the ground, the risks of increased soil infiltration and runoff of nitrogen and phosphorus due to reduced dry matter[34] and more soluble nitrogen and phosphorus persists.[35]

Due to the nature of this general permit, these harms will be more pronounced. The Digester General Permit opens a one-size-fits all, direct pathway for digester construction and operation, with very little consideration of the particularities or location of each operation. While industry is likely to target larger, finishing operations,[36] the general permit does not bar any operation with coverage under the existing swine animal waste general permit from receiving coverage under the Digester General Permit. Therefore, the Digester General Permit opens the door to the same harms detailed in the original complaint on a vastly greater scale by potentially authorizing the construction and operation of digester systems at more than 2,000 hog operations, most of which are in eastern North Carolina.

B. Disproportionate Harm Expected for Communities of Color

The disproportionate burden of pollution shouldered by Black, Latino and Native American families living around industrial hog operations in North Carolina is well documented.[37] To date, DEQ's approach to permitting digesters at hog operations has disproportionately impacted communities of color as well as low-wealth communities, making this a significant environmental justice issue. At a special meeting in fall 2021 regarding pollution and adverse health outcomes affecting families living near hog operations in eastern North Carolina and ahead of DEQ's permitting process for the Digester General Permit, members of DEQ's Environmental Justice & Equity Advisory Board adopted a strongly worded recommendation expressing "significant concerns about the pollution and public health implications of this general permitting scheme" and requesting DEQ to "take steps to protect . . . families, their health, and the environment."[38] DEQ ignored these recommendations altogether when issuing the Digester General Permit.

An independent analysis of DEQ's permitting of hog operations with digesters as of May 2022 (see Table 1 below) indicates that the facilities operating under individual biogas permits located in predominantly white, more affluent communities each employ animal waste management systems that are significantly more protective of the environment and local communities than those used by facilities located in and around majority Black, Latino, and Native American communities and communities with higher poverty levels.[39] Not only are biogas producing hog operations disproportionately sited in and around communities of color and low-wealth communities, but the facilities in and around these communities pollute more than those sited in whiter, more affluent communities.[40]

DEQ's own Environmental Justice Report for the Digester General Permit showed that the five North Carolina counties with the highest number of hog operations per square mile have higher percentages of nonwhite and Hispanic or Latino populations compared to the state.[43] With the overwhelming majority of industrial hog operations being located in just a few counties, if even a small percentage of these operations seek coverage under the Digester General

[41] Statewide, the total percentage of people of color is 39.5 percent; highlighting in Table 1 indicates percentage of people of color is 50 percent or greater. *See* Draft Environmental Justice Report, N.C. [43] N.C. DEP'T OF ENV'T QUALITY, ENVIRONMENTAL JUSTICE REPORT: BIOGAS DIGESTER GENERAL PERMIT DEVELOPMENT 10 (June 30, 2022) [hereinafter EJ Report], https://deq.nc.gov/media/30369/download?attachment (Exhibit 15).

Permit, Black, Latino and Native American families are likely to be disproportionately impacted.[44]

C. DEQ Failed to Consider These Harms in Issuing the Digester General Permit

In issuing the Digester General Permit, DEQ failed to act in accordance with its obligations under Title VI. While DEQ did publish an environmental justice report, that report did not evaluate many other metrics, including for example the presence of other polluting industries in eastern North Carolina, nor did it appear to influence DEQ's permitting decision; DEQ provided no additional safeguards in the permit to ensure that communities protected under Title VI are not disproportionately impacted by the permit.[45] Further, DEQ did not acknowledge, much less respond, to Complainants' comments about the disparate permitting of hog operations in white communities versus permitting of hog operations in communities of color.[46] And despite being on notice of the pending investigation of the 2021 complaint and past enforcement action regarding DEQ's permitting of hog operations, DEQ did not include conditions in the permit necessary to protect nearby communities and the environment.

Complaints submitted written comments to DEQ detailing the potential Title VI violations associated with the Digester General Permit.[47] DEQ responded that it "operates a robust nondiscrimination program that complies with EPA's Title VI regulations."[48] DEQ further stated that it is "monitoring the national landscape of the discussion and guidance around cumulative impact scoring, including what other states are implementing, and engaging in discussions with EPA staff regarding the anticipated release of cumulative impact analysis guidance documents by the end of 2022."[49] DEQ made no changes to the final permit based on these comments.[50]

Commenters, including Complainants, also raised concerns to DEQ about the cumulative impacts and environmental injustices associated with the Digester General Permit.[51] Completely ignoring evidence of ongoing impacts to surface waters and air quality from industrial hog operations,[52] DEQ responded that because permitted operations cannot discharge to surface waters, the Digester General Permit "do[es] not increase the potential for impacts to surface

water and groundwater."[53] DEQ claims that prohibiting discharges to waterways "ensure[s] protection of human health and the environment, regardless of race, color or national origin."[54] This response is unmoored to the facts on the ground and the best available science and ignores DEQ's mandatory obligations under Title VI of the Civil Rights Act.

V. Relief Requested

Complainants request that DEQ's actions and impacts from issuance of the Digester General Permit be included and considered during the informal resolution process and further investigation into this matter.

VI. Conclusion

For all the reasons outlined above, Complainants request that OECRC bring DEQ into compliance with Title VI of the Civil Rights Act of 1964 and EPA's implementing regulations.

Thank you for your consideration of this additional information. We look forward to continuing discussions with OECRC regarding this matter.

Sincerely,

Blakely E. Hildebrand

BUSINESS

California's Green-Energy Subsidies Spur a Gold Rush in Cow Manure

A lucrative state incentive to make natural gas from dairy waste is attracting companies from Amazon to Chevron

By Phred Dvorak Follow *Photographs by Jennifer Emerling for The Wall Street Journal*

Feb. 19, 2022 9:00 am ET

Clean Energy Fuels Corp., CLNE **-3.88%** ▼ a major distributor of natural gas made from waste, found a way to boost its earnings by millions of dollars, virtually overnight.

All it had to do was switch the main biofuel it supplies to power cars and trucks in California—currently a type of natural gas produced with methane emissions from garbage—to a chemically identical gas produced from the manure of cows.

California's clean-fuels grading system gives cow-poop gas a much better score—and much higher subsidies—than landfill gas. So that simple substitution could net Clean Energy an additional $70 million in earnings before interest, taxes, depreciation and amortization by 2026, the company estimates.

Together with European energy giants BP PLC and TotalEnergies SE, Clean Energy is pouring hundreds of millions of dollars into gas production on dairy farms to milk that advantage. A host of developers, financiers and carbon-conscious corporations, from Chevron Corp. to Amazon.com Inc., AMZN **1.41%** ▲ are looking to buy or produce the fuel as well.

"It is like magic," said Andrew Littlefair, Clean Energy's president and chief executive, of the projected earnings boost.

The surging interest in dairy renewable natural gas, as it is called, shows how incentives can spur action to address the emissions linked to climate change—and sometimes unintended consequences as well. Until a few years ago, the gas, which is interchangeable with conventional natural gas and can replace dirtier fuels like diesel, was a niche product that was too expensive to make commercially.

Now, California's generous subsidies have prompted what some observers are dubbing a manure gold rush. One developer said he showed up at a dairy only to discover that the farmer had gotten more than 10 pitches for business tie-ups already. Others said competition for business has gotten so heated that some developers are promising to pay farmers a fixed amount per cow—a risky setup if the price of the California credits plummets.

David Ribiero, co-owner of Rib-Arrow Dairy in central California, said methane sales have finally become economically feasible.

Driving the boom is California's Low-Carbon Fuel Standard. The standard requires companies that sell transportation fuels in the state to lower their products' carbon intensity—the

carbon dioxide emitted during manufacture, distribution and consumption. Companies that exceed the carbon-intensity maximums have to buy offset credits, each of which represents a metric ton of emissions. Those with low-scoring fuels generate credits, whose price goes up and down depending on demand.

The lowest carbon-intensity scores go to fuels that keep warming gases out of the air—particularly methane, a greenhouse gas that can be 84 times more potent in trapping heat than carbon dioxide, according to the Intergovernmental Panel on Climate Change, the scientific group that helps the United Nations evaluate the state of research on the issue.

Other waste sources such as landfills produce methane, too. But California already requires landfills to curb methane emissions while farms don't have to, and thus they emit more. So capturing the methane from decomposing manure at dairies to make truck fuel cuts net emissions a lot, and reaps some of the best scores of all.

U.S. regulators haven't generally imposed controls on methane emissions from livestock, since they are tough to implement and politically sensitive.

California Bioenergy LLC, which develops projects to make energy out of manure, in 2016 received the first provisional carbon-intensity score—around negative 270—for a dairy-gas facility. Diesel by comparison has an average carbon-intensity score of more than 100. CalBio, as it is known, now has 41 dairy-gas projects in operation and another 60-odd projects in development.

Its latest project to go online is the 1,500-cow Rib-Arrow Dairy in central California, where manure is now flushed from the floor of the stalls into a covered lagoon, called a digester, so the methane can be collected for processing rather than released into the air. That raw biogas, which is around 60% methane and the remainder mostly carbon dioxide, is piped to a central facility that collects gas from a cluster of dairies in the area and purifies it for injection into the local utility's pipeline.

David Ribeiro, a third-generation co-owner of Rib-Arrow, said he had been approached by digester salesmen before, but that adding the gas sales to the environmental benefits finally made everything economically feasible: "We're like, 'Wow, this makes sense.'"

There are 116 such facilities currently operating in the U.S.—more than half of which went online last year—and another 121 planned or in construction, according to the Coalition for Renewable Natural Gas, a nonprofit that promotes gas made from waste. Analysts say

thousands more dairies could support such plants, which can reduce foul odors in addition to capturing emissions.

The market is likely to remain small compared with the U.S.'s overall appetite for natural gas in homes, businesses and transport. Even in an optimistic scenario, biogas from manure would supply only around 3% of today's demand by 2040, according to a 2019 study commissioned by the American Gas Foundation.

Still, money is pouring in from big companies looking to lower their carbon footprints quickly —as well as entrepreneurs smelling a business opportunity. Clean Energy said it is working on more than a billion dollars worth of deals through its dairy-gas joint ventures with BP and Total, and that it hopes to channel more than $2 billion in investment by 2026.

California-based Chevron has committed around $500 million to develop renewable natural-gas supply, starting with dairies. A Chevron investor presentation in September showed plans for a national network of as many as "190,000 milking cow equivalents" and forecast double-digit returns. Amazon has inked a deal with Clean Energy to buy biogas for its massive trucking fleet; it declined to comment.

At a California Bioenergy plant, methane is separated from carbon dioxide before it is injected into a local utility's pipeline.

The entire separation process happens over the course of a minute.

More than half of California's methane is released from dairy and livestock manure, and by cow burps. The state has vowed to lower greenhouse gas emissions by 40% compared with

1990 levels by 2030, and it is focusing on methane reductions in particular. It is also targeting a 20% reduction in the carbon intensity of its transportation fuel relative to 2010, and has so far managed to cut it by more than 7%.

“From our perspective, the program is working to drive private investment” to accomplish the state’s environmental goals, said Matthew Botill, the division chief at California’s Air Resources Board who oversees the state’s low-carbon fuel standard and other climate change programs.

California officials said the program doesn’t cost the state money because its market-based mechanism results in producers and consumers of higher-carbon fuels effectively paying the incentives to the producers and consumers of low-carbon fuels.

Oregon and the Canadian province of British Columbia are implementing similar fuel standards, and a number of other states are considering them, too. The federal government issues its own, less-lucrative, subsidies for low-carbon fuels.

California’s aggressive incentive system is producing some odd results. One dairy that was already using digesters to collect methane and produce electricity from its manure—the 35,000-cow Threemile Canyon Farms in Oregon—got a relatively high carbon-intensity score of negative 189 when it shifted to making gas for California, since it had fewer emissions to reduce.

“The manure management practices on the farm were so good…that they were penalized a bit,” said Ben Vitale, CEO of Resilient Infrastructure Group, which owns Threemile’s gas plant.

Financiers at Cresta Fund Management, a Texas-based private-equity fund that has two renewable natural gas producers in its portfolio, said they have seen an increasing number of entrepreneurs with little experience in the area trying to raise money for dairy-gas projects.

“We had some authors pitch us,” said John Skrinar, Cresta’s director of sustainable investments. “The reality is, it’s a lot more complicated than just show up, put a swimming pool in the ground, shovel a bunch of cow manure into it, and make a fortune.”

At Rib-Arrow Dairy, water used in the methane-capture process is stored in this lagoon. The water will eventually be used for cow feed and fertilizer.

FALSE PROMISES and HIDDEN IMPACTS of DAIRY DIGESTERS

The Basics

Dairy digesters are facilities that create biogas, also known as biomethane, from wet manure from large, confined animal feeding operations (CAFOs). The gas is then injected into pipelines or, possibly, used as transportation fuel. Biomethane is not clean; burning manure-produced gas emits the same air contaminants as the combustion of fossil fuel, and releases other harmful pollutants into the air and water that are unique to factory farms.

False Promises

Dairy digesters are the only option to deal with the methane released from wet manure in dairy operations.

REALITY: Dry manure management techniques and other alternative practices can prevent the creation of methane.

Dairy digesters are addressing the full scope of greenhouse gas emissions from dairies.

REALITY: Dairy digesters do nothing to address enteric (intestinal) methane emissions from cows, or other GHG emissions from dairies.

Dairy digesters are accessible to small dairies, and helping them thrive..

REALITY: Only large dairies can provide enough manure to make adopting digester technology worthwhile, allowing big dairy to only get bigger.

Who's Paying the Price?

Community and environmental impacts: CAFOs produce serious environmental impacts, particularly in nearby communities, by contaminating groundwater, emitting air contaminants beyond methane, attracting heavy-duty truck traffic and producing odors. These pollution, public health, and social equity effects fall especially on disadvantaged rural communities.

Unintended consequences: Increased funding for dairy digesters is likely to exacerbate these problems by incentivizing even larger dairy operations, and in effect, bigger herd sizes and higher concentrations of cows that produce more harmful methane.

Manure Pit, or Money Pit?: Despite hundreds of millions of dollars in grant funds to support digester development and operations, dairy digester proponents themselves note the need for continued grants and rate-payer subsidies to sustain the industry.

Whose cash cow?

Only two digester developers (California Bioenergy & Maas Energy Works) have received 100% of the <$110 million from CDFA's digester program in 2017 & 2018. Plus, Maas and CalBio received 95.5% of $319 million from the CPUC for six digester cluster projects. CalBio gets another $26.5 million in loans for digesters from the Aliso Canyon Settlement.

White Oak Farms in Fremont, NC operates an anaerobic digester that turns hog waste and parts into electricity for sale to Duke Energy. In May, it ruptured, sending thousands of gallons of gray slurry across the farm and toward nearby Nahunta Swamp. BY KEVIN KEISTER

FREMONT

The state inspector knew immediately there was trouble at White Oak Farms.

When she visited the Wayne County farm on Feb. 3, the N.C. Department of Environmental Quality inspector saw a thick layer of hay laden with charcoal-colored foam in a ditch. That foam seemed to have oozed from under a black tarp covering a hog waste lagoon where manure was combined with unusual ingredients like liquified hog carcasses and discarded hot dogs and deli meat in a slurry to generate methane.

The farm's owners, including a former member of the National Pork Board, had not reported a spill.

In a notice of violation dated Feb. 18, two weeks after the inspection, David May, a supervisor in DEQ's Washington Regional Office, wrote that the inspector couldn't tell how deep the foam was. But, May wrote, "the inspector stepped in that area sinking at least 4 inches on the edge."

White Oak Farms' problems were just beginning.

Four months later, on May 30, the black cover ruptured, sending an estimated three million gallons of the gelatinous gray foam across the farm and toward nearby

reached wetlands.

finalizing a permit making it easier for anaerobic digesters to get environmental approval and easier for farmers to install them.

Riverkeepers argue that DEQ's regulation of White Oak Farms shows the department is not prepared for a potentially exponential increase of digesters on North Carolina's hog farms.

They learned about the White Oaks Farms spill on Aug. 3, more than two months after it began, when Sound Rivers' Neuse Riverkeeper Samantha Krop flew over the facility. Krop saw that the black bubble that was supposed to be capturing gas appeared deflated, with water pooled across its surface.

Krop also noticed that there was no vegetation around the lagoon and that it looked like dirt had been moved around southeast of the digester, where the property borders Nahunta Swamp.

"It just didn't look right," Krop said. "It didn't look like they were functioning properly."

'ONE REALLY TERRIBLE SCIENCE EXPERIMENT'

The Feb. 3 inspection focused on the covered lagoon, a system called an anaerobic digester.

Farmers pump manure and other unwanted material into the lagoon, where it decomposes, releasing methane and other gases. Digesters capture those gases, particularly methane, and use them to produce electricity or purified natural gas.

In recent years, agricultural groups and environmentalists have debated the use of anaerobic digesters in North Carolina.

Get 93% off your first month. Subscribe today for $1.

permit allowing most future digesters to move quickly through the environmental approval process.

The N.C. Pork Council and other agricultural interests argue that covering waste lagoons reduces odor and prevents emissions of methane, a potent greenhouse gas. They also offer farmers a revenue stream.

In a written statement, Roy Lee Lindsey, the Pork Council's CEO, said, "Digesters are a safe and proven technology that provide significant environmental benefits. While this situation was unfortunate, it is an isolated incident and should not discourage us from continuing to pursue renewable natural gas projects in North Carolina."

Environmental groups argue that digesters effectively lock in what they call a primitive waste management system in which hog manure and urine are washed into lagoons before being sprayed across nearby fields. The White Oak Farms spill demonstrates the risks digesters pose, said Blakely Hildebrand, a senior attorney at the Southern Environmental Law Center.

"It goes to show that these digester systems aren't the environmental, climate silver bullet that the hog industry has painted them to be," Hildebrand said.

revealed publicly that staff had been monitoring an active digester spill.

That general permit would not have covered White Oak Farms' digester. It only covers systems that process hog manure and urine, said Anna Gurney, a DEQ spokeswoman, not those that add other things into the slurry like White Oak Farms' liquid pig carcasses, cast-off hot dogs and deli meat.

Despite the digester debate, almost nobody knew a North Carolina hog operation was already operating by adding hogs and meat products to the manure under its black plastic balloon.

"We have never heard of this before. We started asking around and nobody else in the environmental advocate world that we're in has heard of this, either," Jill Howell, the Pamlico-Tar riverkeeper, told The News & Observer.

Howell continued, "It just all seems very strange and like one really terrible science experiment."

'THIS IS THE ULTIMATE RECYCLING'

Deborah and Todd Ballance started hog farming in 1990, first as contract growers. When Coharie Hog Farm folded in 2009, the Ballances bought the pigs on their farm and went independent.

Get 93% off your first month. Subscribe today for $1.

“Since the farm was built by my husband’s grandfather our family has always strived to look to the future in order to do what is best for our family, our animals, our community, and our environment,” Deborah Ballance wrote in an email to The News & Observer. “We believe strongly in being sustainable and that is why we covered our lagoon and captured the methane for electricity.”

The N.C. Pork Report, a N.C. Pork Council trade publication, profiled the Ballance family in 2017, shortly after then-U.S. Agriculture Secretary Sonny Perdue named Deborah Ballance to the National Pork Board.

The story says Deborah and Todd met in first grade and farm land passed down by Todd’s grandfather. It also discusses the possibilities their efforts to turn manure into energy offer.

Deborah Ballance told the Pork Report, “I think we basically reinvent ourselves every three years. You need to keep your ear to the ground and see what you need to be doing next or thinking about next, and that’s what we try to do.”

The Ballance family had long been exploring how to generate revenue from hog waste, according to decades of permitting documents reviewed by The News & Observer.

Get 93% off your first month. Subscribe today for $1.

fields. The farm planned to keep hog manure from reaching the lagoon and spread it on a field.

Evaluations were underway, the permit said, of compacting solid waste and using it as animal feed. A 1997 application said, “White Oak Farms is very confident that the waste will become suitable animal feed. When it is converted to animal feed it will no longer be land applied.”

In 2002, the farm said the manure capture system hadn’t worked as advertised and the equipment used to move liquid between lagoons had proven noisy and expensive to operate.

At that point, the farm was permitted to have 5,500 sows.

They wanted more hogs, but were limited by a moratorium on new or expanded hog operations the N.C. General Assembly made permanent in 2007 — a moratorium rooted in The News & Observer’s Pulitzer Prize-winning “Boss Hog” series that showed how a lack of regulation around the industry was leading to environmental threats near some farms.

Get 93% off your first month. Subscribe today for $1.

that 0.2% of the state's energy come from swine waste by 2018.

In 2013, White Oaks Farms asked DEQ: Could it add 60,000 hogs as long as it added an anaerobic digester, controlling odor, groundwater contamination and other environmental impacts?

“Despite a moratorium in place in North Carolina on new hog farm construction, we found the ideal way to expand with finishing floors. We could build a methane digester and sell power to the power company,” the Ballance family wrote in a 2017 USDA loan application.

Electricity generated by White Oak Farms could power about 3,000 homes on Duke Energy’s grid, according to the application.

“We will take our hog waste and mortality and use it as fuel! This is the ultimate recycling,” the Ballances wrote.

DEQ approved the permit in October 2013. In later permits, the regulatory agency would require the Ballances to expand in phases, starting with 15,000 hogs

Get 93% off your first month. Subscribe today for $1.

contaminants from seeping into soil or groundwater. The permit approved by DEQ in 2013 and again in 2017 says the 8.75-million gallon anaerobic digester is "earthen-lined."

"It's a very prescriptive standard," Hildebrand said. "These performance standards aren't vague."

The digester started operating in April 2019. Randy Wheeless, a Duke Energy spokesman, said the utility has bought power from White Oak Farms since 2019. Over that period, it has averaged enough electricity to power about 400 homes.

Energy generated by hog waste, Wheeless said, is more expensive than energy from solar farms or natural gas.

Wheeless said, "It's a premium product because there's just not that many facilities in a position to do that, and you still have a law in place in the state that says utilities shall buy or secure that type of power."

CHANGING SOURCES

In 2020, DEQ approved an updated permit limiting what could go into the digester each day. The farm could add swine waste, up to 20,000 pounds of food waste like hot dogs or deli meat from Smithfield's Kinston plant, and 210,000 pounds of dead pigs.

With that approval, the farm started adding the dead pigs in July 2020. They later reported the pigs caused significantly higher methane production.

Around the same time, the COVID-19 pandemic was impacting the farm's operation. Despite having permission to add as many as 15,000 hogs, the farm instead found itself operating with 100 sows at most.

That impacted the digester, too.

Get 93% off your first month. Subscribe today for $1.

In a year-end report, the Ballances wrote, “With swine production and processing decreasing industrywide, the facility has experienced a temporary change from a manure dominated digester feed source to primarily a food waste and mortality source.”

In other words, the farm was putting more dead pigs and cast-off meat into the digester than hog waste, despite its permit explicitly stating that manure should be the main additive.

The trend continued throughout 2021, with the number of hogs dwindling from 81 to 50.

Still, the digester was operating well on mostly dead pigs and unwanted meat. In 2021’s year-end report, the Ballance family wrote, “From an energy production standpoint, the facility experienced its best period to date.”

The farm submitted that report on Jan. 31, 2022. Three days later, the DEQ inspector found signs of the digester’s unreported spill.

During a February inspection, a N.C. Department of Environmental Quality inspector found signs that a discharge of foam from an anaerobic digester on White Oak Farms had not been reported. Those signs included foam on top of the digester. *N.C. Department of Environmental Quality*

THE SPILL

The bubble burst in the middle of the night.

White Oak Farms' digester ruptured around 3 a.m. on May 30, according to a press release the farm sent to local newspapers.

Later, the farm would write that "an unexpectedly severe digester foaming event" started with a fissure on the northern face of the black plastic covering. That's also where the DEQ inspector identified the previous, unreported spill during her February inspection.

Get 93% off your first month. Subscribe today for $1.

A “thick foam” made of hog matter, liquid and gases gurgled out of the digester. According to the farm’s accounts, the foam ran across a field and reached a forest that contains wetlands.

The farm maintains none of the foam reached Nahunta Swamp on its southern boundary.

DEQ staff conducted several inspections over the ensuing weeks. On June 3, they saw foam on nearby surface water, possibly including Nahunta Swamp. That foam was cleaned up when staff returned on June 7.

The spill was still active on June 23, according to a notice of violation DEQ issued in July. That notice said DEQ staff had detected “objectionable” odors and air quality and saw foam coming out of concrete structures on the digester’s western edge.

The covering on a Wayne County lagoon broke open in late May, sending more than four swimming pools’ of foam across White Oak Farms in Fremont. The damaged anaerobic digester is shown here on August 3. Samantha Krop *Sound Rivers*

But an N.C. State professor who studies anaerobic digesters said the dead hogs and cast-off meat could have played a role.

Adding materials containing fat, oil and grease to anaerobic digesters can significantly heighten biogas production, Mahmoud Sharara wrote in an email to The News & Observer. But at the same time, long chain fatty acids within the so-called FOG material can cause a layer of foam and crust to develop on top of the slurry.

Sharara, an agricultural and biological engineering professor, does not have first-hand knowledge of the White Oak Farms facility.

It is possible, Sharara added, that the higher levels of gas could have been incompatible with existing infrastructure like the generator or motor that processed the gas. Pressure could have built up underneath the cover, he wrote, ultimately causing the rupture and allowing the foam to spill out.

Get 93% off your first month. Subscribe today for $1.

began immediate cleanup. We have repaired our cover and complied with every requirement and suggestion made by DEQ. We will continue to consult with our engineer and scientific consultants to perfect our unique operation."

As of June 13, there were no hogs on White Oak Farms.

LINGERING QUESTIONS

After learning of the spill via Krop's flight, riverkeepers dug into the permit record. They were alarmed that they hadn't heard of the spill before and that the public notice requirements allowed White Oak Farms to report the spill without specific details.

"There was no reference to what was in the wastewater foam, there was no acknowledgment that it was swine waste or dead hogs or food waste product," Howell said. "It's like a bare, bare bones public notice."

North Carolina laws require any facility that spills more than 15,000 gallons of animal waste into the state's surface waters or wetlands to issue a press release in both the county where the spill happened and the county immediately downstream. That press release needs to say where and when the spill happened, how much waste was discharged, how long the spill went on and what the facility is doing to prevent further spills.

Hildebrand, of the Southern Environmental Law Center, said White Oak Farms followed the law, but that the law or DEQ should require information about a spill to be spread futher than a public notice in a local newspaper's classified section.

"Especially in this day and age. I think the law could be better, the requirements could and should be better around public notification," Hildebrand said, adding that DEQ is able to issue public notification itself or require operators that have spills to issue more widespread notification.

Get 93% off your first month. Subscribe today for $1.

Advocates also wonder whether DEQ can adequately regulate digesters, particularly considering Dominion Energy and Smithfield's joint $500 million Align RNG initiative that is already forging ahead in Duplin and Sampson counties.

With more digesters appearing likely to come online in the coming years, Howell and other advocates are concerned that DEQ field staff have not been specifically trained to inspect them.

Gurney, the DEQ spokesman, said the Division of Water Resources "will conduct additional training for regional inspectors as needed as facilities are covered by the Digester General Permit."

The department's field staff noted violations at White Oak Farms and issued notices of violation, including the one in February, but Howell argues that wasn't enough to convince the farm to correct the problems.

"DEQ's enforcement was insufficient in all of this," Howell said.

On July 5, DEQ issued another notice of violation against White Oak Farms. The department said the Ballance family's improper operation of the digester had resulted in the spill and impacts on nearby surface waters and wetlands.

Get 93% off your first month. Subscribe today for $1.

than 20,000 pounds of food waste on a given day, exceeding the amounts allowed in its permit. It noted that ammonia levels in wells between the digester and Nahunta Swamp were more than 12 times higher than the allowable concentration.

In response to DEQ, the Ballance family said they stopped adding new material to the digester “at least three weeks” before the spill happened.

The Ballance family also mentioned its plans to build another digester.

Ideally, they wrote, the manure and meat products that had spilled from the old digester could be pumped into the new one to “seed the digestion process.” The new digester would have a synthetic liner to protect groundwater, as well as a berm on its southern side to contain any future spills.

Relation Between Nitrate in Water Wells and Potential Sources in the Lower Yakima Valley, Washington

U.S. EPA Region 10
March 2013

ERRATA

Relation Between Nitrate in Water Wells and Potential Sources in the Lower Yakima Valley, Washington

In 2010, the U.S. Environmental Protection Agency (EPA) conducted a study to identify potential sources of nitrate contamination in groundwater and residential drinking water wells in the Lower Yakima Valley in central Washington State. EPA released a report on this study in September 2012, entitled "Relation Between Nitrate in Water Wells and Potential Sources in the Lower Yakima Valley, Washington" ("EPA 2012 Report"). The EPA 2012 Report was assigned document number EPA-910-12-003. Further review of the document identified errors in the report. Corrections to the EPA 2012 Report are summarized below and incorporated into this version of the document which has been assigned document number EPA-910-R-13-004. The page numbers below refer to the new document (EPA-910-R-13-004) and may vary slightly from the page number in the original version of the report (EPA-910-R-12-003).

ACKNOWLEDGEMENTS

Page xvi, third paragraph: During the public input period, David Tarkalson, PhD requested that his name and affiliation be removed from the final report. His name and affiliation were removed from the acknowledgements section.

Page xvi, third paragraph: Roger Burke, PhD of U.S. EPA's Office of Research and Development also provided an independent third party review of the EPA 2012 Report. His name has been added to the acknowledgements section.

EXECUTIVE SUMMARY

Page ES-3: The following was added to the end of the "Study Design" section.

> "A discussion of the quality assurance and quality control (QA/QC) procedures and a summary of the data validation process are presented in Appendix E. Uncertainties and limitations with analytical data were noted in Appendix E and described in detail in the data validation memoranda. Data usability is also indicated in the data summary tables by inclusion of data qualifiers."

Page ES-11, Table ES-1: Deleted "DVM" from the reference to the Sunny Dene Ranch.

SECTION I: INTRODUCTION

Page 1, 4th paragraph: The following revisions were made in response to comments made by the *Yakima Herald Republic* during the public input period and to correct the statement attributed to a letter from the *Yakima Herald Republic*:

> "According to the Herald, following the series, the reporter received a number of inquiries from citizens asking whether EPA could take action under the Safe Drinking Water Act (SDWA). These inquiries prompted the reporter to send a letter to EPA asking whether the agency would consider invoking emergency authority under Section 1431 of the SDWA to address the problem."

SECTION II: PURPOSE AND SCOPE

Page 2: The following sentence was added to the end of the second paragraph.

> "A data usability review and validation independent of the laboratories were conducted by EPA and are discussed in Appendix E."

SECTION VI: THREE STUDY PHASES

Page 15, Table 1: Deleted "DVM" from the reference to the Sunny Dene Ranch.

SECTION VII: PHASE 3: COMPOUNDS AND ANALYTICAL TECHNIQUES

Page 28: Inserted "δ" in several places.

SECTION VIII: QUALITY ASSURANCE AND QUALITY CONTROL

Page 29: In the fifth sentence, the word "is" was changed to "are".

SECTION IX: ANALYTICAL RESULTS AND DISCUSSION

Page 30: The following was added after the first full paragraph:

> "A data usability review and validation independent of the laboratories were conducted by EPA and are discussed in Appendix E. Data usability is indicated in the data summary tables by inclusion of data qualifiers. The data qualifiers are defined in the footnotes of the data summary tables and further explained in Appendix E. A discussion of data bias, where it could be determined, also is included in Appendix E."

Page 31: The following was added to the first paragraph:

> "A farm with 2500 dairy cattle is similar in waste load to a city of 411,000 people (EPA 2004). A difference lies in the fact that human waste is treated before discharge into the environment, but animal waste is either not treated at all or minimally treated before discharge into the environment (EPA 2004)."

Page 32: Replaced the first two full paragraphs with the following:

> "NRCS Washington recommends avoiding the use of "agricultural waste storage ponds" (lagoons), unless no reasonable alternative exists, at locations like the Haak Dairy where there is an aquifer that serves as a domestic water supply (NRCS Washington 2004). If no reasonable alternative exists, consideration should be given to the following: 1) a clay liner designed in accordance with procedures of Agricultural Waste Management Field Handbook Appendix 10D ("NRCS Appendix 10D") with a thickness and coefficient of permeability so that specific discharge is less than 1×10^{-6} cm/sec; 2) a flexible membrane liner over a clay liner; 3) a geosynthetic clay liner (GCL) flexible membrane liner; or 4) a concrete liner designed in accordance with slab on grade criteria for fabricated structures requiring water tightness."
>
> "EPA estimated the seepage from lagoons for the Haak Dairy using unit seepage rates from NRCS Appendix 10D and from a field study by Ham and DeSutter (Ham 2002). Lagoon design should consider unit seepage rates in addition to other factors such as state and local requirements and site-specific conditions (e.g., groundwater flow and depth to groundwater) (NRCS 2008). State regulations for specific discharge range from about 500 gallons per acre per day (1/56 inch or 0.45 mm per day) to about 6,800 gallons per acre per day (1/4 inch or 6.35 mm per day)

> (NRCS 2008). Applying a unit seepage rate of 500 gallons per acre per day to the surface area of the Haak Dairy lagoons equates to an approximate seepage volume of 1,080,000 gallons per year, the equivalent of about 1.6 volumes of an Olympic-size swimming pool annually (Table 7)."

Page 32, Table 7: Corrected the title of the third column to read: "Estimated Lagoon System Leakage, Based on Unit Seepage Rate of 500 Gallons per Acre per Day (gallons per year)" and a footnote (formerly footnote number 24) was deleted.

Page 33: Replaced the second paragraph with the following:

> "The seepage rate of 0.45 mm per day falls within the Ham and DeSutter range of 0.2 to 2.4 mm per day. Leakage rates for the Haak Dairy lagoons would likely be greater than the above estimates if the lagoons are unlined. If the lagoons are lined with a plastic liner, the actual leakage rates could be lower, although plastic liners can be punctured during construction and lagoon maintenance, especially during periodic dredging activities."

Page 43, first paragraph: The second sentence was modified as follows: "Total coliform, but not *E. coli* or fecal coliform, was detected in WW-04."

Page 44: Table 16 has been corrected to reflect that atrazine was not detected in WW-03.

Page 48, Table 18: Corrected the title of the third column to read: "Estimated Lagoon System Leakage, Based on Unit Seepage Rate of 500 Gallons per Acre per Day (gallons per year)" and a footnote (formerly footnote number 30) was deleted.

Page 48: Replaced the second paragraph with the following:

> "As discussed previously, the NRCS Washington recommends avoiding the use of "agricultural waste storage ponds" (lagoons), unless no reasonable alternative exists, at locations like the Dairy Cluster where there is an aquifer that serves as a domestic water supply (NRCS Washington 2004). Assuming the same unit seepage rate as for the Haak Dairy (500 gallons per acre per day), seepage volume at the Dairy Cluster is approximately 7,391,000 gallons per year. This is the equivalent volume of about 11 Olympic-size swimming pools annually."

Page 51: The second sentence in the first paragraph was corrected as follows: "Figures 11 and 15 show the sample locations for the Dairy Cluster."

Page 58, Table 22: Deleted the reference to WW-18 which is not associated with the Dairy Cluster.

Page 65, Table 26: Deleted "DVM" from the reference to the Sunny Dene Ranch.

Page 67, Table 29: Added the units of measure to the bentazon result for SO-11 so that it reads "38 ug/kg".

SECTION X: STUDY LIMITATIONS AND UNCERTAINTIES

Page 79: The following was added to this section.

> "A discussion of the QA/QC procedures and a summary of the data validation process are presented in Appendix E. Uncertainties and limitations with analytical data were noted in Appendix E and described in detail in the data validation memoranda. Data usability is also indicated in the data summary tables by inclusion of data qualifiers."

SECTION XII: REFERENCES

Page 88: Reference EPA 2010b has been corrected to read "Yakima Basin Nitrate Study Phase 3 – Comprehensive Analytical Source Tracer Sampling April 2010 Sampling Event. Quality Assurance Project Plan. EPA Region 10. April 8, 2010."

APPENDICES

Appendix C

Table C11: Deleted the "h" from the end of the word "anti-inflammatory" after the word "naproxen".

Tables C11, C12 and C14: The sample type designations were corrected for samples SO-11 through SO-16.

Appendix E, pages E-8 and E-9, Section 1: The following paragraphs were added.

> Microbial Source Tracking
>
> Microbial Source Tracking (MST) analysis was performed on nine lagoon and four wastewater treatment plant samples using a polymerase chain reaction (PCR) technique. All quality control measures passed including laboratory QC, sterility controls, and blank analyses. Samples were assessed on a present (P) / absent (A) basis for *Bacteroides* species with possible source identification of general *Bacteroides* (GB), human (H), ruminant (R), or both human and ruminant (H/R).
>
> Bacteria
>
> Twenty-one well water, six lagoon, and three wastewater treatment plant samples were analyzed for total coliform by Standard Method (SM) 9222B, fecal coliform by SM 9221E, and/or *E. coli* by SM 9221F. All quality control measures passed including holding time requirements, laboratory QC, sterility controls, and blank analyses. All lagoon and wastewater treatment samples were qualified estimated ("J") for *E. coli* as the method, SM 9221F, has not been approved for use under the Clean Water Act (CWA).

Appendix E, page E-13, Section 6: The second sentence in the third paragraph was revised by replacing "changed" with "replaced".

ACKNOWLEDGEMENTS

This report was initiated as part of an U.S. Environmental Protection Agency (EPA) Regionally Applied Research Effort (RARE) project with additional support from EPA's regional and national Office of Compliance and Enforcement, including the Environmental Justice Showcase Community pilot program.

The report was prepared by EPA Region 10's Office of Environmental Assessment with assistance from Region 10's Offices of Water and Watersheds, Regional Counsel, Ecosystems, Tribal, and Public Affairs, Compliance and Enforcement and EPA's National Risk Management Research Laboratory at the Robert S. Kerr Environmental Research Center in Ada, Oklahoma.

We would like to acknowledge the following individuals who provided an independent third party review of the report: Megan Young, PhD, U.S. Geological Survey; Stephen Kraemer, PhD, U.S. EPA Office of Research and Development; Roger Burke, PhD, U.S. EPA Office of Research and Development; and Lorraine Edmond, U.S. EPA Region 10.

(This page intentionally left blank.)

EXECUTIVE SUMMARY

Several investigations relating to nitrate contamination in the Lower Yakima Valley in Washington State have been conducted over the last 30 years. These studies have repeatedly shown nitrate levels in drinking water above the U.S. Environmental Protection Agency (EPA) maximum contaminant level (MCL) of 10 mg/L. Nitrate contamination in groundwater is primarily a health risk for rural populations who rely on private wells for drinking water.

From February through April 2010, EPA conducted sampling of drinking water wells and potential sources of nitrate contamination in the Lower Yakima Valley, which is in Yakima County in central Washington State. The Yakama Reservation composes a large percentage of the Lower Yakima Valley**.** EPA's effort entailed collecting over 331 samples from residential drinking water wells for nitrate and bacteria, and multi-parameter sampling on 29 water wells (26 residential drinking water wells and three dairy supply wells), 12 dairy lagoons (15 samples), 11 soil samples (five at dairy application fields and six at irrigated and fertilized crop fields[1]), five dairy manure pile samples, and three wastewater treatment plant (WWTP) influent samples. This report presents the results of these sampling efforts.

Purpose and Scope

The primary purpose of this study was to investigate the contribution from various land uses to the high nitrate levels in groundwater and residential drinking water wells, which is the predominant source of drinking water for many residents in the Lower Yakima Valley.

The study included sampling of residential drinking water wells, dairy supply water wells, and three sources of nitrate: dairies; irrigated cropland; and residential septic systems. In addition to nitrate and other forms of nitrogen, EPA analyzed samples for a variety of chemicals to evaluate whether chemicals other than nitrate can be used to identify likely sources of the nitrate contamination in the groundwater and drinking water wells.

EPA analyzed samples for chemicals that were expected to be associated with one or more of the sources. These included pharmaceuticals (both veterinary and human medications), personal care products, steroids and hormones, pesticides and herbicides, as well as other indicators of water quality such as total nitrogen and major ions such as chloride and calcium.

EPA also used microbial analysis to determine whether the water wells, lagoons and WWTP influent samples exhibited fecal contamination. If the samples were found to have fecal contamination, then microbial source tracking (MST) was performed to identify the source of the fecal contamination (in this case, human or ruminant). Isotopic analysis of water wells was conducted to identify the possible origin of the nitrate in water wells. Age dating analysis on the well samples was conducted to estimate the time since water infiltrated to the aquifer.

[1] In this report, "application field" refers to fields owned or leased by the dairies and "crop field" or "irrigated cropland" refers to fields owned or leased by other farmers. Both application fields and crop fields could receive applications of manure and/or synthetic fertilizer.

The Yakima Basin is a watershed of great diversity in climate, vegetation, and land use. More than 30 percent of the Yakima Basin is forested, 30 percent is sage-steppe rangeland, and 28 percent is in agricultural production (USGS 2009). This investigation focused on a portion of the Yakima Basin referred to as the Lower Yakima Valley**.** This broad valley is bounded by basalt ridgelines to the north and south, the Cascade Mountains to the west, and encompasses two counties (Yakima and Benton) and the million-acre Confederated Tribes and Bands of the Yakama Nation Reservation (Yakama Reservation). The study area includes portions of the Toppenish Basin (western area) and the Benton Basin (eastern area) along the Yakima River. Together, both areas cover approximately 368,600 acres within Yakima County. The Lower Yakima Valley is home to about 75,000 people, of which about one-third (24,000) use private, unregulated residential wells (Ecology 2010).

Background

Nitrate is an inorganic compound and a naturally occurring form of nitrogen. On a national scale nitrate is typically found in shallow groundwater at concentrations up to 1.1 mg/L (Nolan and Hitt 2003). Higher nitrate concentrations than this usually indicates that human activities have contributed additional nitrate to the groundwater. Nitrate is highly soluble in water and mobile in soil, which makes it relatively easy for nitrogen from a variety of point and non-point sources to move through the soil and into the groundwater as nitrate.

EPA has established a MCL for nitrate in drinking water of 10 mg/L under the Safe Drinking Water Act (SDWA). EPA regulates nitrate in public drinking water systems because nitrate concentrations greater than the MCL may cause health problems. Exposure to excess nitrate can result in methemoglobinemia (blue-baby syndrome) in infants and susceptible individuals, which can lead to death in extreme cases (Ward 2005). Some studies have shown a positive association between long-term exposure to nitrate in drinking water and risk of cancer and certain reproductive outcomes, while other studies have shown no association (Ward 2005).

Study Design

EPA designed a three-phased study. The purpose of Phase 1 was to identify the major sources of nitrogen in the study area, based on historical records and available information. During Phase 1 EPA combined information on land use with some simple calculations to estimate the amount of potential nitrogen available from several sources. The estimates indicate that three sources — livestock (primarily dairy cattle), irrigated cropland, and septic and biosolids — account for as much as 98 percent of the nitrogen available for application to the land (EPA 2012b). Livestock (primarily dairy cattle) account for about 65 percent, irrigated cropland for about 30 percent and septic and biosolids about 3 percent of the available nitrogen. The estimates do not account for losses of nitrogen from various biological, physical, and chemical processes and do not account for crop utilization. Based on the estimates developed in Phase 1, EPA focused the Phase 2 and 3 sampling on the three predominant sources: dairies; irrigated cropland; and residential septic systems.

The objectives of Phase 2 were to: (1) evaluate nitrate contamination of groundwater at locations downgradient of the three types of sources identified in Phase 1; (2) assist in identifying sampling locations for Phase 3 sampling; and (3) provide residents with information on the nitrate levels in their drinking water wells. EPA conducted Phase 2 sampling between February 22 and March 6, 2010. EPA

found that water from wells at 67 homes, about 20 percent of the wells sampled in Phase 2, exceeded the MCL of 10 mg/L for nitrate.

The results of Phases 1 and 2 were used in Phase 3 to identify residential drinking water wells with high nitrate concentrations and potential upgradient sources of nitrogen. Once these locations were identified, EPA collected and analyzed samples from the potential source areas and downgradient residential drinking water wells. EPA also collected and analyzed representative drinking water wells upgradient of the dairies (See Table ES-1). No drinking water wells upgradient of the crop fields or septic systems were sampled.

EPA analyzed samples for nearly 200 chemicals and used several analytical techniques to investigate the source of high levels of nitrate in water wells. The chemical analyses and analytical techniques were grouped as follows: general chemistry; microbial data; organic compounds; isotopic analysis; and age dating. The data for each of the analytical techniques were evaluated independently in an effort to identify the specific likely sources of the high nitrate concentrations found in residential drinking water wells (See Table ES-2). A discussion of the quality assurance and quality control (QA/QC) procedures and a summary of the data validation process are presented in Appendix E. Uncertainties and limitations with analytical data were noted in Appendix E and described in detail in the data validation memoranda. Data usability is also indicated in the data summary tables by inclusion of data qualifiers.

Phase 3 Study Limitations and Uncertainties

Several limitations in the study are important to note. First, water well samples were collected from existing wells. No new wells were installed for this study. Information on the depths and screened intervals of the water wells is known for about a third of the wells that were sampled. In this report, designations of upgradient and downgradient are based on regional groundwater flow data from the United States Geological Survey (USGS). Lack of complete well information limits our ability to verify if the wells upgradient and downgradient of the sources draw water from the same water bearing zone.

In addition, EPA lacks complete information regarding the dairies in this study. EPA requested information on specific aspects of the dairy operations and the physical setting; however, the dairies in this study did not provide this information. This information would have contributed to a more complete understanding of the dairy facilities, practices, and use of specific chemicals. It would have allowed EPA to provide actual values, or narrower ranges of estimates, for certain parameters in this report (for example, numbers of animals, quantities of nitrogen, estimates of lagoon leakage). EPA has, however, referenced general information regarding dairy operations, and specific information regarding the dairies in the Yakima Valley to the extent it was available.

Finally, EPA has limited information about the irrigated crop fields in this study. Verifiable, detailed crop production data, in terms of nutrients applied (the likely source of nitrate associated with irrigated crops), were not available and no irrigation data were available. EPA has included information about the crop fields to the extent it was available. In addition, the irrigated crop fields are surrounded by similar agricultural uses, and many are situated downgradient of dairies, making more difficult EPA's ability to discern the source of nitrate in drinking water wells downgradient of the irrigated crop fields.

Phase 3 Study Results

As stated previously, the primary purpose of the study was to investigate the contribution of various land uses to the high nitrate levels in groundwater and residential drinking water wells in the Lower Yakima Valley. The four main source areas sampled and the results of the sampling are discussed below.

Haak Dairy

The R&M Haak Dairy (Haak Dairy) is located in an agricultural area north of the Yakima River, about four miles north of the community of Sunnyside. EPA selected the Haak Dairy for this study because it generally met the criteria identified in the study plan for inclusion. Specifically, the dairy has a high concentration of animals per acre; Washington State Department of Agriculture (WSDA) inspectors noted in their reports for the Haak Dairy that elevated levels of nitrogen were detected in its application fields[2] in the past (WSDA 2012); it is located near the northern edge of cultivated land use and in a location with relatively few upgradient potential sources of nitrogen; and drinking water wells downgradient of the Haak Dairy showed levels of nitrate significantly above the MCL.

Several locations were sampled at the Haak Dairy during Phase 3: one dairy supply well; one dairy manure pile located on the dairy; two dairy lagoons; and one dairy application field. During Phase 3 EPA also resampled three of the residential drinking water wells downgradient of the Haak Dairy that exceeded the MCL during Phase 2, and one residential drinking water well upgradient of the Haak Dairy.

Based on data from the WSDA (WSDA 2010), EPA estimated that the Haak Dairy generates an estimated 84 to 210 tons of nitrogen per year after accounting for losses from volatilization and denitrification during storage.[3] Based on information from a field study by Ham and DeSutter (Ham 2002) and from the Natural Resources Conservation Service (NRCS) Agricultural Waste Management Field Handbook (NRCS 2008), EPA estimated that the Haak Dairy lagoons leak 482,000 to 5,873,000 gallons[4] of liquid waste per year into the underlying soils. The Dairy applies solid and liquid animal wastes to its application fields. WSDA inspectors documented that the Haak Dairy has also used inorganic fertilizer on its application fields (WSDA 2012).

Concentrations of total nitrogen increase in the direction of groundwater flow from the upgradient well to three residential drinking water wells downgradient of the Haak Dairy, with the highest concentrations detected in the dairy sources (lagoons, manure pile, and application field). The upgradient well was within the expected background concentration for nitrate.

The three residential drinking water wells downgradient of the Haak Dairy all have nitrate levels greater than EPA's MCL of 10 mg/L. Also, the concentration of six major ions (chloride, calcium, magnesium, potassium, sodium, and sulfate) show a pattern of increasing concentrations from the upgradient well to

[2] See footnote 1.

[3] The Washington State Department of Agriculture can only provide information on the number of animals at each dairy in ranges. Because of this, the estimated amount of nitrogen generated at the Haak Dairy is presented as a range. See Section IX.A for a more detailed discussion.

[4] The EPA estimates are presented in a range because the Ham 2002 study provided a range of lagoon leakage rates. See Section IX.A for a more detailed discussion.

the three downgradient residential wells, with the highest concentrations in the dairy sources (with the exception of sulfate which was not detected in two lagoon samples). Alkalinity and the metals barium and zinc show a similar pattern. Information on the construction and depth of the upgradient and one downgradient well would be helpful to provide additional certainty regarding the likely sources. However, review of the data suggests that the Haak Dairy is a likely source of the nitrate and major ions in the three downgradient residential drinking water wells. Inorganic fertilizer used on the Haak Dairy's application fields also could be a source of the nitrate observed in the downgradient wells.

Two pharmaceuticals, tetracycline and monensin, were detected in all the dairy source samples collected at the Haak Dairy, indicating that these compounds are used by the dairy. Tetracycline was detected in two of the three downgradient residential drinking water wells but not in the upgradient well, indicating the Haak Dairy is a likely source. Monensin was detected in the upgradient well and in the three downgradient residential drinking water wells, although the upgradient residential drinking water well had a higher concentration than two of the downgradient water wells. It is possible that the Haak Dairy is a source of the monensin detected in the downgradient residential drinking water wells. Given the presence of monensin in the upgradient well, another source of monensin is likely. Additional information that supports that the dairy may be a source of monensin is that it was not detected in samples collected from the WWTP influents that were collected as surrogates for rural septic systems.

The isotopic data provide strong evidence that animal (human or non-human) waste is the likely dominant source of the nitrate contamination in at least one of the residential wells downgradient of the Haak Dairy. However, since isotopic analysis alone cannot differentiate between human and non-human waste, both could be sources of the nitrate in this downgradient well.

Several compounds that tend to be less mobile in groundwater than nitrate and some of the major ions were detected in Haak Dairy lagoon, manure pile, and application field samples, but not detected in the downgradient water wells (for example, trace organics and hormones). Fecal coliform was not detected in any of the wells downgradient of the Haak Dairy.

Dairy Cluster

The "Dairy Cluster" refers to a group of dairies, including George DeRuyter & Son Dairy, D and A Dairy, Cow Palace 1 and 2, Liberty Dairy, and Bosma Dairy, situated north of the Yakima River. The Dairy Cluster is located about 2 miles north of the town of Liberty, near the northern edge of the irrigated area in the Yakima Valley. The facilities generally consist of cow pens, milking parlors, animal waste lagoons, and animal waste application fields.[5] Irrigation ditches run through the dairy properties.

EPA selected these dairies for this study because they generally met the criteria identified in the study plan for inclusion. Specifically, the Dairy Cluster has; a high concentration of animals per acre; WSDA inspectors noted in their reports for the Dairy Cluster that elevated levels of nitrogen were detected in its application fields in the past (WSDA 2012); the dairies are located near the northern edge of cultivated

[5] See footnote 1.

land in the Lower Yakima Valley with relatively few upgradient potential sources of nitrogen; and drinking water wells downgradient of the dairies showed levels of nitrate significantly above the MCL.

Several locations were sampled in the Dairy Cluster during Phase 3: three dairy supply wells; four dairy manure piles; ten dairy lagoons; and four dairy application field samples. During Phase 3, EPA also sampled eight downgradient residential drinking water wells that were found to exceed the MCL for nitrate during Phase 2, and one upgradient residential drinking water well.[6]

Based on data from the Washington State Department of Agriculture (WSDA 2010), EPA estimated that the Dairy Cluster generates more than 2,055 tons of nitrogen per year after accounting for losses from volatilization and denitrification. Based on information from a field study by Ham and DeSutter (Ham 2002) and from the NRCS Agricultural Waste Management Field Handbook (NRCS 2008), EPA estimated that the Dairy Cluster lagoons leak between 3,330,000 and 39,600,000 gallons[7] of liquid lagoon waste per year into the underlying soils. All the dairies in the Dairy Cluster apply animal wastes as fertilizer onto application fields that they own or lease according to WSDA inspection reports (WSDA 2012). The dairies, (except for Cow Palace) also reported using synthetic fertilizer on some of their application fields.

Similar to the Haak Dairy, the results from the sampling indicate that the concentration of total nitrogen increases in the direction of groundwater flow from the upgradient well to the downgradient residential drinking water wells, with the highest concentrations detected in the dairy sources.[8] The nitrate concentrations in the residential drinking water wells downgradient of the Dairy Cluster, with the exception of one unusually deep residential drinking water well, have nitrate levels greater than the EPA MCL. The concentrations of five major ions, especially calcium and chloride, increase between the upgradient well and the downgradient residential drinking water well, with the highest concentrations in the dairy sources. Alkalinity and barium show a similar pattern. The relatively young water in the upgradient well that EPA sampled in Phase 3 suggests that it is a shallow well.

As with the Haak Dairy, information on the construction and depth of the upgradient well and five of the downgradient water wells sampled during Phase 3 would be helpful to clarify the contribution of sources to the increased concentrations measured in the downgradient wells. However, the information presented above indicates that the Dairy Cluster is a likely source of the nitrate, major ions, and other substances in the downgradient residential drinking water wells.

The pharmaceuticals tetracycline and monensin were detected in all but one of the dairy source samples, which indicate they are used by the dairies in the Dairy Cluster. Tetracycline was detected in two of the downgradient residential drinking water wells, two dairy supply wells, dairy lagoons, manure piles and application fields. The concentration of tetracycline found in the upgradient residential well was similar

[6] The results for samples that EPA collected during Phase 2 from other wells located upgradient of the Dairy Cluster were also below the MCL for nitrate. Those data are included in this report in Table C1 in Appendix C (sample locations WW-22103 and WW-22085).

[7] The EPA estimates are presented in a range because the Ham 2002 study provided a range of lagoon leakage rates. See Section IX.B for a more detailed discussion.

[8] See footnote 6.

to the concentrations detected in two of the downgradient residential wells. The dairies are a possible source of the tetracycline in the downgradient wells. However, given the concentration in the upgradient well, another source of tetracycline likely exists.

Monensin was detected in two of the downgradient residential drinking water wells, two dairy supply wells, dairy lagoons, manure piles and application fields. The Dairy Cluster is a likely source of monensin because this antibiotic is used in dairy cows but not by people. Monensin was not detected in samples from the WWTP influents which were collected as surrogates for residential septic systems, further supporting that the dairies are the likely source.

The hormone testosterone was detected in downgradient residential drinking water wells and dairy sources. The concentration of testosterone found in the upgradient residential drinking water well is similar to the concentrations detected in the downgradient water wells. The dairies are a possible source of the testosterone in the downgradient wells; however, given the concentration in the upgradient well, another source of testosterone is likely.

The isotopic data provide strong evidence that animal (human or non-human) waste is the likely dominant source of the nitrate in at least two of the residential drinking water wells downgradient of the Dairy Cluster. Because isotopic analysis cannot differentiate between human and non-human waste, both could be sources of the nitrate in this downgradient well.

Several other compounds that are generally less mobile in groundwater than nitrate and some of the major ions, were detected in the Dairy Cluster sources, but not in the residential drinking water wells (for example, the trace organics). Fecal coliform was not detected in any of the residential drinking water wells.

Irrigated Cropland

Nitrogen-rich fertilizers, such as inorganic synthetic fertilizer and manure, are applied to irrigated cropland and are a possible source of nitrate in drinking water wells. In Phase 3, EPA sampled six irrigated crop fields[9] (two mint, two hops, and two corn) and six residential drinking water wells downgradient of these fields.

Irrigated crop field soil samples were analyzed for several forms of nitrogen, pesticides, pharmaceuticals, and hormones. They were not analyzed for major ions, trace inorganic elements, perchlorate, microbiology, trace organics, isotopic analysis, or age dating.

The six water wells downgradient from the irrigated crop fields and sampled by EPA during Phase 3 all had nitrate levels greater than the MCL. Several organic compounds were detected in the crop soil samples, but only bentazon and monensin were detected in a water well and its associated crop soil sample. Bentazon was detected in two water wells and the associated soil samples. These results indicate that bentazon was applied to the crop field and is likely migrating to groundwater and the water wells. Monensin was the only veterinary pharmaceutical detected in one well and also in an associated soil

[9] See footnote 1.

sample collected from a hop field. Possible manure application to the hop field could account for the monensin detected in the downgradient residential well. The isotopic analysis indicated that the dominant source of nitrate for one residential drinking water well was synthetic fertilizer.

Residential Septic Systems

Four residential wells located in Mabton, Harrah, and Sunnyside were selected for evaluation of impacts from septic systems. However, all the residential drinking water wells sampled as part of Phase 3 of this study were analyzed for the same suite of chemicals. EPA also collected influent samples from three WWTPs located in Zillah, Mabton, and Toppenish. These WWTP samples were collected to serve as a surrogate for septic system waste.[10] The WWTP influent had no actual or potential hydrogeological connection with the residential wells. This approach was used to determine whether the same compounds are detected in WWTP influent samples and in water wells with high nitrate concentrations in areas with a high density of septic systems or whether these wells are affected by other sources.

The majority of the trace organics (e.g., personal care products) and wastewater pharmaceuticals were detected in the WWTP influent samples but only two of these compounds were detected in the residential drinking water wells sampled by EPA in Phase 3. Specifically, bis-(2-ethylhexyl) phthalate (DEHP, a plasticizer) was detected in four residential drinking water wells and DEET (an insect repellant) was detected in one residential drinking water well. These results indicate that these compounds are being used and can be found in wastewater, but with a few exceptions are not reaching residential drinking water wells.

Four veterinary pharmaceutical compounds were detected in the WWTP influent samples, three of which were also detected in one or more of the residential drinking water wells in the study. Specifically, sulfamethazine (used for cattle, poultry and swine) was detected in two residential drinking water wells, sulfamethoxazole (used for people) in one residential drinking water well, and tetracycline (used for people, cattle, and several other animals) in six residential drinking water wells.

There were 10 additional veterinary pharmaceuticals detected in residential drinking water wells, but not detected in WWTP influent samples. Monensin (used for cattle and poultry) and virginiamycin (used in poultry and swine) were the most frequently detected veterinary pharmaceuticals: monensin was detected in nine residential drinking water wells and virginiamycin in four. Monensin and virginiamycin were not detected in the WWTP influent samples. Given the results, septic systems are a possible source of tetracycline and sulfamethoxazole in the residential drinking water wells.

Of the 20 hormones analyzed, 14 were detected in at least one WWTP influent sample. Of those 14 hormones, seven were detected in residential drinking water wells. Testosterone and androsterone were the most frequently detected hormones: testosterone was detected in nine wells and androsterone was detected in four wells. Given both testosterone and androsterone are natural sex hormones it is possible they came from septic systems in proximity to the residential drinking water wells.

[10] EPA recognizes that the WWTP influent may contain substances that are not found in residential septic systems (for example they may also receive commercial and industrial waste streams). The WWTPs sampled serve rural communities and are sufficiently similar to residential septic systems for the purpose of EPA's study.

Microbial source tracking was not performed because there were no detectable concentrations of fecal coliform in any of the residential drinking water wells. The isotopic data provide strong evidence that animal (human or non-human) waste is a likely dominant source of the nitrate contamination in at least six residential drinking water wells. Since isotopic analysis cannot differentiate between human and non-human waste, both could be sources of the nitrate in this downgradient well based on the isotopic analysis.

Conclusions

Nitrate levels above EPA's drinking water standard in residential drinking water wells in the Lower Yakima Valley are well documented. The objective of this study was to evaluate the effectiveness of certain chemicals, microbial parameters, or analytical techniques to identify specific sources of the high nitrate levels detected in residential drinking water wells.

Many of the chemicals and microbial parameters evaluated in this study were not detected in the residential drinking water wells. There were no detections of fecal coliform in the Phase 3 residential drinking water wells, although high concentrations were found in the dairy sources and WWTP influent. There were very few trace inorganic elements, trace organics, or wastewater pharmaceuticals detected in the residential drinking water wells or crop field soil samples, although many of these chemicals were detected in the dairy sources and WWTPs. The isotopic data provide some indication of the likely nitrate sources for seven of the 25 residential wells tested (six animal waste and one synthetic fertilizer). Although the isotopic analysis identified animal waste as the source of the nitrate in six wells, this analytical technique cannot differentiate between human and non-human waste.

There appears to be a correlation between the age dating data and the depths of the wells for which boring logs are available. The water in the dairy supply wells that are known to be screened in the deeper basaltic aquifer is older than in the downgradient residential wells which are commonly screened in the shallower alluvial aquifer. The age dating results were not useful to determine when the nitrate contamination was introduced into the well.

Given the historic and current volumes of wastes generated and stored by dairies, and the application of nitrogen-rich fertilizers including dairy waste in the Lower Yakima Valley, it is expected that dairies are a likely source of high nitrate levels in downgradient drinking water wells. The total nitrogen, major ions, alkalinity and barium data provide strong evidence that the dairies evaluated in this study are likely sources of the high nitrate levels in the drinking water wells downgradient of the dairies. Additional information that supports this conclusion includes: there are few potential sources of nitrogen located upgradient of the dairies; the dairy lagoons are likely leaking large quantities of nitrogen-rich liquid into the subsurface; and Washington State Department of Agriculture inspectors have reported elevated levels of nitrogen in application fields of the dairies in the study.

Given the historic and current application of nitrogen-rich fertilizers in the Lower Yakima Valley, it is expected that irrigated crop fields would be a likely source of high nitrate levels in downgradient drinking water wells. The data collected in this study provide some corroboration that irrigated crop fields are a likely a source of nitrate in groundwater. The data supporting this conclusion is not as strong for the crop fields as it is for the dairies. The reasons for this include: lack of upgradient well data; the irrigated crop fields sampled are situated amongst other agricultural uses, including upgradient dairy operations; fewer

analytes detected in both the crop field samples and the corresponding downgradient wells; more limited information about crop field operations; and the crop fields' positions on the landscape relative to other potential sources.

While septic systems could be a source of nitrate in drinking water wells, there is insufficient information from this study to support this conclusion.

The high nitrate levels in residential drinking water wells in the Lower Yakima Valley are likely coming from several sources. This study attempted to identify those sources. In some cases it was possible to identify likely or possible sources of the nitrate contamination.

Evaluating actions to reduce nitrate concentrations in residential drinking water wells to safe levels is beyond the scope of this report. Although actions to reduce nitrate are needed, it may take many years to reduce the nitrate levels in residential drinking water wells to safe levels because of the extent of the nitrate contamination in the Lower Yakima Valley and the persistence of nitrate in the environment.

Table ES-1: Overview of the Study Design to Investigate Suspected Sources of Nitrate in Water Wells Near Dairies, Irrigated Cropland, and Septic Systems

Source Type	Sampling Area	Upgradient Well Sample	Supply Well Sample	Potential Sources of Nitrate	Downgradient Well Sample	Study Design [c,d]
Dairies	Haak Dairy	WW-01	WW-02	Lagoons (LG-01 to LG-03) Manure Piles (SO-01) Application Fields (SO-02)	WW-03 to WW-05	Compare chemicals and microbiology in upgradient wells with sources and downgradient wells. Conduct isotopic analyses for water wells and lagoons and age dating for water wells.
	Dairy Cluster	WW-06[a]	WW-07, WW-08, and WW-09	Lagoons (LG-04 to LG-15) Manure Piles (SO-03, SO-05, SO-07, and SO-09) Application Fields[b] (SO-04, SO-06, SO-08, and SO-10)	WW-10 to WW-17	
Irrigated Croplands	Schilperoort Farm	NA	NA	SO-11 (Mint)	WW-23	Compare chemicals in downgradient wells with soil samples from associated crop fields.
	Havilah Farm	NA	NA	SO-12 (Mint)	WW-24	
	Wheeler Farm	NA	NA	SO-13 (Corn)	WW-25	
	Sunny Dene Ranch	NA	NA	SO-14 (Corn)	WW-28	
	Golden Gate Hops	NA	NA	SO-15 (Hops)	WW-26	
	Golden Gate Hops	NA	NA	SO-16 (Hops)	WW-27	
Septic Systems	Mabton	NA	NA	Septic Systems	WW-21	Compare chemicals in water wells with influent from 3 wastewater treatment plants (Zillah, Mabton, and Toppenish).
	Harrah	NA	NA	Septic Systems	WW-19	
	Sunnyside	NA	NA	Septic Systems	WW-20 and WW-22	

[a]As noted above, in footnote 2 of the text, EPA collected samples from other wells located upgradient of the Dairy Cluster which were also below the MCL for nitrate during Phase 2. That data is included in this report in Table C1 in Appendix C (sample location WW-22103 and WW-22085).

[b]Thirty soil samples per application field or crop field were collected at a depth of 1 inch and composited to obtain a representative sample.

[c]Two additional residential wells, WW-18 and WW-30, were sampled during this study, but were not included in the original study design or listed in this table. The results for these two wells are documented in Section IX.E of this report.

[d]See Table C2 in Appendix C and Table ES-2 for a description of the analytes for each source.

NA – not applicable.

Table ES-2: Summary of the Chemical Groups and Media Included in Phase 3 of the Study

Compound or Analytical Technique (Number of Compounds Analyzed)	Water Wells	Dairy Lagoons	Dairy Manure Piles	Dairy Application Fields	WWTP Influent[c]	Crop Soils
General Chemistry						
Nitrate (1)	X		X	X		X
Other Nitrogen Forms[a]	X	X	X	X	X	X
Major Ions (9)	X	X			X	
Trace Elements (12)	X	X			X	
Perchlorate (1)	X					
Microbiology						
Bacteria (3)	X	X			X	
Microbial Source Tracking[b]	X	X			X	
Organic compounds						
Pesticides (50)	X	X[d]	X	X	X[d]	X
Trace Organics (69)	X	X			X	
Pharmaceuticals (31)	X	X	X	X	X	X
Hormones (20)	X	X	X	X	X	X
Analytical Techniques						
Isotopic Analysis (2)	X	X			X	
Age Dating (NA)	X					

[a]Other nitrogen forms for water wells and lagoons include ammonia, TKN, and nitrate plus nitrite. Other forms of nitrogen for manure piles, dairy application fields, and crop samples include extractable nitrate, extractable ammonia, and total nitrogen by combustion.

[b] Microbial source tracking was conducted only if there was an indication of fecal contamination detected in the sample.

[c]Majority of influent from households but contribution from businesses and industry also expected.

[d]Because of matrix interference, results for pesticide analysis for lagoon and wastewater treatment influent samples were not useable.

X – the compound or analytical technique was analyzed.

NA – not applicable

I. INTRODUCTION

This report presents the results for sampling conducted from February through April 2010 by the U.S. Environmental Protection Agency (EPA) in the Lower Yakima Valley in central Washington State. The primary purpose of this study was to investigate the contribution of various sources from nearby land uses to the high nitrate levels in groundwater and residential drinking water wells. The study looked at three likely sources of nitrate: dairies; irrigated cropland; and residential septic systems.

EPA used standard investigation and analytical methods as well as several research methods. The sampling was conducted as part of an EPA Regionally Applied Research Effort (RARE)[11] grant (EPA 2009). Funding was also provided by EPA's regional and national Offices of Compliance and Enforcement including the Environmental Justice (EJ) Showcase Community pilot program.[12] Yakima is one of ten communities in the nation to receive focused attention on disproportionate environmental health burdens.

EPA's sampling effort in the Lower Yakima Valley was partially in response to concerns raised by several agencies and community members who participated in the EPA Community Action for a Renewed Environment (CARE) cooperative agreement with the Northwest Communities Education Center (NCEC) in Yakima County, Washington. The objective of the cooperative agreement was to assist the Yakima Valley community to establish its priorities for environmental health concerns. Numerous meetings were held over a 2-year period from 2007 to 2009. One of the outcomes from the cooperative agreement was that community members identified their top three environmental health priorities as groundwater contamination, asthma, and children's exposure to pesticides.

In October 2008, the *Yakima Herald Republic* ran a series of articles titled "Hidden Wells, Dirty Water" that examined a long history of groundwater contamination affecting public and private drinking water wells, primarily in the Lower Yakima Valley. According to the Herald, following the series, the reporter received a number of inquiries from citizens asking whether EPA could take action under the Safe Drinking Water Act (SDWA). These inquiries prompted the reporter to send a letter to EPA asking whether the agency would consider invoking emergency authority under Section 1431 of the SDWA to address the problem. Section 1431 (42 U.S.C. § 300i) authorizes EPA to take action when, among other things, a contaminant is present or may enter a public water system or underground source of drinking water that may present an imminent and substantial endangerment to human health.

EPA facilitated the formation of a workgroup consisting of representatives from state and local agencies, EPA, and the community. The workgroup released a report in February 2010 entitled, "Lower Yakima Valley Groundwater Quality: Preliminary Assessment and Recommendations" (Ecology 2010) ("February 2010 Report"). One of the recommendations identified in the February 2010 Report was to conduct an investigation to gather information to try to link high nitrate levels in drinking water wells with specific sources.

---

[11] The purpose of the RARE program is to provide EPA Regional Offices with support for near-term applied research projects and enhance interactions and connections between regional staff and EPA's Office of Research and Development.

[12] The EJ showcase projects focus on low income and minority communities experiencing disproportionate impacts from environmental health burdens.

The February 2010 Report documented that groundwater data collected in the Lower Yakima Valley from 1990 to 2008 indicated that as many as 12 percent of private wells had nitrate levels above EPA's drinking water standard for nitrate (10 mg/L) and about 20 percent of private wells demonstrated bacterial contamination (Ecology 2010).

II. PURPOSE AND SCOPE

As discussed above, the primary purpose of this study was to collect data to investigate the contribution of various sources from nearby land uses to the high nitrate levels in groundwater and residential drinking water wells. To accomplish this, EPA sampled and analyzed sources of nitrate (dairies, irrigated croplands, and residential septic systems) and private residential drinking water wells for a variety of chemicals to evaluate whether chemicals, including nitrate, could be used to link the nitrate contamination in groundwater and drinking water wells to the sources. The analysis included chemicals that are expected to be associated with one or more of the likely sources, such as pharmaceuticals (both veterinary and human medications), personal care products, steroids and hormones, pesticides and herbicides, as well as other indicators of water quality such as nitrogen and major ions such as chloride and calcium.

EPA also used microbial analysis to determine whether the water wells, lagoons and WWTP influent samples exhibited fecal contamination. If the samples were found to have fecal contamination, then microbial source tracking (MST) was performed to identify the source of the fecal contamination (in this case, human or ruminant). In addition, EPA performed isotopic analysis for the water wells to identify the possible origin of the nitrate in water wells. Finally, an age dating analysis was completed for the water wells to estimate the time since water infiltrated from the surface to the aquifer. A data usability review and validation independent of the laboratories were conducted by EPA and are discussed in Appendix E.

Figure 1 provides a conceptual site model for the project. The conceptual site model (in conjunction with Figure 2 – Nitrogen Cycle) provides a graphic description of how nitrate from various sources can reach groundwater and eventually drinking water wells. This study evaluated three likely sources of the nitrate contamination in drinking water wells (dairies, irrigated cropland, and residential septic systems). The main sources of nitrogen from the dairies include dairy waste lagoons; manure piles; and manure and synthetic fertilizers applied to application fields on land controlled by the dairies. For irrigated crop fields[13], the main source is the synthetic fertilizers and manure[14] applied to the land to promote plant growth. For septic systems, it is the human waste that can migrate from septic systems into nearby drinking water wells.

As described in Figure 2 (Nitrogen Cycle), nitrogen is applied to the land from different sources. The different forms of nitrogen typically migrate through the unsaturated silts, sands, and gravels and arrive at the water table via preferential pathways. The nitrogen is converted to nitrate through chemical and biological processes. Groundwater contaminated with nitrate can be pumped up in drinking water wells

[13] In this report, "application field" refers to fields owned or leased by the dairies and "crop field" or "cropland" refers to fields owned or leased by other farmers. Both application fields and crop fields could receive applications of manure and/or synthetic fertilizer.

[14] Although initially EPA considered irrigated cropland to be a potential source of nitrate because of synthetic fertilizer application, through this study, it became clear that several of the irrigated crop fields sampled had also received manure applications.

where people consume the water. Groundwater contaminated with nitrate can also migrate to surface water such as the Yakima River.

The scope of this study consists of an area approximately 40 miles long and ranging between 10 and 25 miles wide. The study area includes parts of Yakima County and the Confederated Tribes and Bands of the Yakama Nation Reservation (Yakama Reservation). EPA identified areas with some of the highest nitrate concentrations to conduct additional sampling to evaluate whether other chemicals are traveling with the nitrate from the sources to the groundwater and drinking water wells. This report includes the results for the sampling of 331 wells for nitrate and bacteria, and multi-parameter analysis of 29 wells (25 residential wells and four dairy supply wells), 12 dairy lagoons (15 samples), 11 soil samples (five at dairy application fields and six at irrigated and fertilized crop fields), five dairy manure samples, and three wastewater treatment plant (WWTP) influent samples. The sampling was conducted from February through April 2010.

Several limitations in the study are important to note. First, water well samples were collected from existing wells. No new wells were installed for this study. Information on the depths and screened intervals of the water wells is known for about a third of the wells that were sampled. In this report, designations of upgradient and downgradient are based on regional groundwater flow data from the United States Geological Survey (USGS). Lack of complete well information limits our ability to verify if the wells upgradient and downgradient of the sources draw water from the same water bearing zone.

In addition, EPA lacks complete information regarding the dairies in this study. EPA requested information on specific aspects of the dairy operations and the physical setting; however, the dairies in this study did not provide this information. This information would have contributed to a more complete understanding of the dairy facilities, practices, and use of specific chemicals. It would have allowed EPA to provide actual values, or narrower ranges of estimates, for certain parameters in this report (for example, numbers of animals, quantities of nitrogen, estimates of lagoon leakage). EPA has, however, referenced general information regarding dairy operations, and specific information regarding the dairies in the Yakima Valley to the extent it was available and the ranges stated in the report are based on actual data.

Finally, EPA has limited information about the irrigated crop fields in this study. Verifiable, detailed crop production data, in terms of nutrients applied (the likely source of nitrate associated with irrigated crops), were not available and no irrigation data were available. EPA has included information about the crop fields to the extent it was available. In addition, the irrigated crop fields are surrounded by similar agricultural uses, and many are situated downgradient of dairies, making more difficult EPA's ability to discern the source of nitrate in drinking water wells downgradient of the irrigated crop fields.

III. BACKGROUND

Nitrate is an inorganic compound that is a naturally occurring form of nitrogen. On a national scale, nitrate is typically found in unimpacted shallow groundwaters at concentrations of up to 1.1 mg/L (Nolan and Hitt 2003). Nitrate concentrations higher than this range typically indicate that human activities have contributed nitrate to the groundwater. Nitrate is highly soluble in water and mobile in soil, which makes it relatively easy for nitrogen from a variety of point and non-point sources to move through the soil and into the groundwater as nitrate.

Nitrate is an acute contaminant, which means an immediate (within hours or days) health effect may result from exposure. EPA has established a maximum contaminant level (MCL) for nitrate in drinking water of 10 mg/L under the SDWA. EPA and state agencies regulate nitrate in public drinking water systems because nitrate concentrations greater than the MCL may cause a number of health problems. Exposure to excess nitrate can result in methemoglobinemia (blue-baby syndrome) in infants and susceptible individuals, which can lead to death in extreme cases (Ward 2005). Methemoglobinemia is caused by the reduction of nitrate to nitrite in the body. Nitrite binds to hemoglobin and lowers the body's ability to carry oxygen in the blood. Some studies have shown a positive association between long-term exposure to nitrate in drinking water and risk of cancer and certain reproductive outcomes, while other studies have shown no association (Ward 2005).

Numerous water quality investigations have been conducted regarding nitrate over the last 30 years in the Lower Yakima Valley, including a 2002 investigation by the Valley Institute for Research and Education (VIRE). All of these studies were summarized in the February 2010 Report prepared by the Washington State Departments of Agriculture, Ecology and Health; Yakima County Public Works Department; and EPA (Ecology 2010). The February 2010 Report found nitrate levels above the EPA MCL of 10 mg/L in about 12 percent of private wells. More than 2,000 people in the study area have private wells that exceed the MCL (Ecology 2010).

Nitrate contamination in groundwater is primarily a health risk for rural populations in the Lower Yakima Valley who rely on private unregulated wells for drinking water. Systems that meet the definition of "public water system" fall under state or federal drinking water regulations. Public water systems are required to test regularly for nitrate, and the data are reported to the Washington State Department of Health. EPA defines a "public water system" under Section 1401(4) of the SDWA, as amended in 1996, 42 U.S.C. § 300f, as:

> "…a system for the provision to the public of water for human consumption through pipes or other constructed conveyances, if such has at least fifteen service connections or regularly serves at least twenty-five people."

The State of Washington has established requirements for systems serving between three and fewer than 15 connections and fewer than 25 people. These water systems are called Group B (Chapter 246-291 of the Washington Administrative Code), and the state Department of Health (DOH) and local health jurisdictions share responsibility for administrating Group B requirements. The DOH does not regulate wells with just one or two connections that are residential systems, but some local jurisdictions regulate these systems. In 2009, the governor and state legislature set a new direction for regulating Group B systems, however, by eliminating all state funding for this program. Users of Group B systems therefore may be at risk.

Owners of drinking water wells that have fewer than three service connections (for example, a single, residential well) are not required to test their drinking water for contaminants. However, EPA and the Washington State Departments of Ecology and Health recommend that rural residents test their well water regularly. If residents choose to test and find contamination levels that exceed the MCL, they are not required to take action to address the situation.

IV. NITROGEN CYCLE

Nitrogen is an essential nutrient that is critical to plant growth. It aids in the formation and function of cellular tissue, proteins, and reproductive structures. Nitrogen can be supplied to plants through the organic decomposition of plants or animal waste products or by the application of synthetic fertilizers. It is present in many chemical forms in the environment, including organic nitrogen, ammonium (NH_4), nitrite (NO_2-), nitrate (NO_3-), and nitrogen gas (N_2). Nitrogen gas composes about 78 percent of the atmosphere. Atmospheric nitrogen must be processed, or fixed, to be used by plants. Some fixation is done by lightning strikes, but the majority of fixation occurs by bacteria. Additional small quantities of nitrate may wash out of the atmosphere from aerosol salt particles from the ocean or dusts from arid regions, or from fossil fuel combustion.

Figure 2 shows the nitrogen cycle (adapted from Pidwirny 2006). The processes of the nitrogen cycle transform nitrogen from one chemical form to another. Important processes in the nitrogen cycle include nitrogen fixation, mineralization, nitrification, and denitrification. The mobility of nitrogen is highly dependent on its form and the matrix it moves through.

In human-influenced systems, there are significant increases in the amount of nitrogen released to the soil, which frequently leaches into groundwater from various land uses, including application of synthetic fertilizers or animal waste. While many fertilizers may be composed of nitrate, urea or ammonia are often used. The urea and ammonia are ultimately converted to nitrate by soil bacteria. Animal wastes are another source of nitrogen frequently applied to the land or directly deposited by animals, and then often managed by people, for example, in lagoons or manure piles at dairies. Infiltrating rain or irrigation water can push excess nitrogen into groundwater from each of these sources, unless it is taken up by plants while still in the shallow subsurface.

Organic nitrogen is nearly immobile. Mineralization occurs when organic nitrogen in the soil is converted by bacteria into ammonium (NH_4). The ammonium is then converted to nitrite and then nitrate by bacteria through nitrification. The ammonium ion, while much less mobile than nitrate due to its positive charge, can be converted to nitrate as it moves through the vadose zone and oxygenated aquifer surfaces.

In soils, nitrate is the most mobile form of nitrogen in both the unsaturated zone and the saturated zone. In the saturated zone, it moves at nearly the speed of the migrating groundwater. The mobility of the nitrate ion is enhanced by the action of negatively charged soil particles, which repel the negatively charged nitrate (Frans 2000). The nitrate can then be converted back into nitrogen gas (N_2) by bacteria through denitrification. Denitrification, a process which can convert nitrate into nitrogen gas by bacteria, can occur in low oxygen environments. In the absence of denitrification, nitrate moves with the groundwater until the groundwater is discharged to surface water, or extracted from a well. For additional information on the nitrogen cycle, see Stumm and Morgan 1996.

V. STUDY AREA

The broad Yakima Basin is bounded by basalt ridgelines to the north and south, the Cascade Mountains to the west. The Yakima Basin is a watershed of great diversity in climate, vegetation, and land use. More than 30 percent of the Yakima Basin is forested, about 30 percent is shrub-steppe rangeland, and about 28

percent is in agricultural production (USGS 2009). The Yakima River flows from its headwaters near the Cascade Mountains crest to its mouth where it joins the Columbia River, 160 miles to the east. Precipitation diminishes to less than 9 inches annually in the rain shadow of the Cascades (Yakima County 2011), and irrigation plays a key role in the viability of agriculture. A series of high mountain reservoirs captures snowmelt, which is released through the Yakima River into a complex set of irrigation diversions and canals throughout the basin. Irrigation is supplied to fields during the March through October growing season in a variety of methods, including flood, furrow, sprinkler, and drip systems.

The study area included a portion of the Yakima Valley, referred to as the Lower Yakima Valley encompassing portions of the Toppenish Basin (western area) and the Benton Basin (eastern area) along the Yakima River (Figure 3). Together, both areas cover approximately 368,600 acres within Yakima County. The Lower Yakima Valley has about 75,000 people, of which about 24,000 use private, unregulated residential wells (Ecology 2010).

In Yakima County, more than 20 percent of the population is at or below the poverty level (less than $17,050 for a family of four in 2000) and a little more than 30 percent of adults have less than a high school diploma. Approximately 41 percent of the population is Hispanic/Latino, which is more than four times the state average of approximately 10 percent. American Indians and Alaskan Natives make up slightly more than 5 percent of the county's population, which is three times the state average of almost 2 percent. English is not the primary language (written or spoken) in many households in Yakima County (U.S. Census 2000). Economic viability depends on high-value agricultural production, irrigation, and a reliable supply of farm laborers. Yakima County leads the nation in production of milk per cow and is a top producer of apples, pears, sweet cherries, mint, and hops in the country (USDA 2007).

A. Western Study Area - The Toppenish Basin

Much of the Toppenish Basin is within the boundaries of the Yakama Indian Reservation. Land ownership in the major floodplain of the Toppenish Basin is a checkerboard of Indian trust, Indian fee, and deeded (privately held) parcels. Land use in this area is mixed, with open range and agriculture predominating. The basin is bordered on the north by the Ahtanum Ridge and on the south by the Toppenish Ridge.

B. Eastern Study Area – The Benton Basin

The Benton Basin includes some reservation lands and the non-reservation lands along the river and on the southeast side of the valley. Approximately 60 percent of the valley population resides in this area, which includes the Yakima County communities of Sunnyside, Granger, Grandview, and Mabton.

The Benton Basin lies in the southeastern part of the Lower Yakima Valley. The western boundary of the basin abuts the eastern boundary of the Toppenish Basin. The southern boundary is bordered by the Horse Heaven Hills, and the northeastern boundary generally follows the northern flank of the Cold Creek Syncline.

C. Geology, Hydrogeology, and Geochemistry of the Study Area

The information presented below, unless otherwise noted, is summarized from the U.S. Geological Survey (USGS) publication "Hydrogeologic Framework of the Yakima River Basin Aquifer System, Washington (USGS 2009).

The Toppenish and Benton Basins consists of fine- and coarse-grained sediments overlying a sequence of three major basalt flows. (See Figure 4 and Figure 5 for a general overview of the hydrogeology for the Toppenish and Benton Basins.) The structural setting for the study area is created by bounding ridges such as the Rattlesnake Mountains, Ahtanum Ridge, Toppenish Ridge, and Horse Heaven Hills. The uppermost basalts of the Saddle Mountain Unit of the Columbia River Basalt Group are typically exposed in these upland ridges. This unit averages more than 500 feet thick. The underlying Wanapum unit averages 600 feet thick. These units are separated by the Mabton Interbed, with an average thickness of 70 feet.

The valley is filled with a variety of sediments that pinch out along the flanks of the ridges. These sediments include Touchet Beds, loess and thick alluvial sands and gravels, and significant thickness of Ellensburg Formation. The thickness of these sedimentary units decreases from an average of more than 500 feet in the Toppenish Basin to less than 200 feet in the lower Benton Basin.

Water is found in fractures and interbeds formed of clinkers, permeable lava, lake deposits or paleo-soils and may occur at significant depths in the upland ridges, such as Horse Heaven Hills, and especially in the basalts. The water table is found at shallower depths as the valley is approached from these ridges. Near the Yakima River, it may be less than 10 feet to water, especially during the irrigation season.

There are two main aquifer types underlying the study area. They include a surficial unconfined to semi-confined alluvial aquifer and an extensive basalt aquifer of great thickness underlying the sedimentary deposits. The basalt aquifer is believed to be semi-isolated from the surficial aquifer and stream systems. Groundwater flow within the surficial aquifer generally follows topography, with natural recharge occurring within the headlands and on the sides of the valley and discharge occurring to the Yakima River. Flow within the uppermost portions of the underlying basaltic aquifer also generally follows this pattern.

However, since the basalts extend to great depths, those deeper basaltic layers may convey waters across local flow divides to more regionally significant discharge locations such as the Columbia River. This pattern produces a major flow direction from northwest to southeast as water moves down the valley parallel to the course of the Yakima River. Other, more localized directions of flow, typically at shallower depths in the uppermost sediments, tend to flow toward the Yakima River. Locally, the flow direction may be modified by geologic structures and by irrigation practices, drains, ditches, canals, and other hydrologic features.

The Lower Yakima Valley is filled with sediments shed by the ridges at the margins of the study area and those deposited in the valley bottom by the Yakima River. These sediments have an internal structure that strongly controls groundwater movement. As the water moves through these sediments, it tends to follow preferential flow paths composed of coarser sediments.

Very frequently, there are 10- to 100-fold differences in groundwater velocities among aquifer materials of such contrasting grain size (Freeze and Cherry 1979). These different preferential flow paths can have different water chemistry, depending on their location below a source of contamination. A well that is located along a preferential flow path may draw a substantial portion of its water from a particular source. A well located on an adjacent, but different, preferential flow path may have markedly different chemistry. For this reason, it is anticipated that upgradient sources of nitrate could produce different downgradient effects in groundwater (such as nitrate in water wells), even in wells from neighboring homes.

Shallower wells in the study area are more likely to be contaminated with nitrate than deeper wells because the sources of most of the nitrogen are anthropogenic activities on the land surface (for example, dairy lagoons and application of synthetic fertilizer). Well depths for about two thirds of the wells used in this study are not known, but the well depths that are known confirm that nitrate concentrations tend to be higher in shallower wells (See Appendix A2). The higher nitrate values in shallower wells were also documented in the February 2010 Report (Ecology 2010). Some of the wells sampled in the study may tap water from the deeper basalts. As water carries nitrogen from the surface through the soil column to the water table, oxygenated conditions in the vadose zone and the aquifer facilitate the formation of nitrate (See Figure 2).

The highest levels of nitrate generally occur in the shallow alluvial aquifer (Ecology 2010). Water-bearing zones in the upper basaltic layers that underlie the alluvial aquifer may be vulnerable to contamination from the shallow aquifer. Basaltic layers develop significant fracture permeability as they cool after volcanic eruption. They are often referred to as "fractured basalts."

Examination of available well logs in the vicinity of the dairies that EPA studied, Haak Dairy and the Dairy Cluster[15], indicates that residential wells are typically screened in the shallow alluvial aquifer or in the upper basalt layers (Appendix A2). Wells screened in these zones are vulnerable to anthropogenic contamination. The fractured condition of the shallow basalts often means the water-bearing layers between the shallow basaltic layers are likely to be in communication with the shallow aquifer. A well pump set in a shallow basaltic water-bearing zone could, depending on conditions, pull contaminated water down through the shallow upper layers.

A brief discussion of the subsurface soil types for the dairies and irrigated cropland is included in the results section. A more detailed soil discussion of soil types for the dairies and irrigated croplands is presented in Appendix B. A complete soil report for each dairy and irrigated crop field was compiled by EPA (EPA 2012a) from the Natural Resources Conservation Service (NRCS) soil data mart (NRCS 2012).

In addition to the variability caused by the physical characteristics of the aquifer, many compounds react with the silts, sands, and gravels of the aquifer in a way that slows their transport. Some compounds, such as nitrate and ions like chloride, tend to minimally adsorb and are transported nearly as fast as the water flows in the aquifer. Nitrate does not break down unless it encounters denitrifying bacteria and

[15] The "Dairy Cluster" refers to a group of dairies, including George DeRuyter & Son Dairy, D and A Dairy, Cow Palace 1 and 2, Liberty Dairy, and Bosma Dairy, situated north of the Yakima River. The Dairy Cluster is located about 2 miles north of the town of Liberty, near the northern edge of the irrigated area in the Yakima Valley.

organic carbon, resulting in a low oxygen or anoxic environment. Other compounds, such as iron or manganese, often participate in chemical reactions and can create relatively immobile minerals, which can change their concentrations as measured in water wells (Fetter 1980).

Organic compounds, which are any gaseous, liquid, or solid chemical compounds containing carbon, are typically less mobile in water than inorganic compounds. Organic compounds tend to adsorb to organic carbon in the aquifer and may be degraded by bacteria and either disappear entirely or may be greatly reduced in concentrations. Even if not broken down, most organic compounds will move much slower than nitrate because they tend to adsorb to other organic matter in the aquifer. As a result, in general, they are unlikely to be transported as far or as fast as the nitrate (Stumm and Morgan 1996).

VI. THREE STUDY PHASES

Several sampling efforts conducted to date in the Lower Yakima Valley by various agencies and groups have focused on nitrate. Although these studies have been useful to document the problem of high nitrate levels in groundwater and private wells, they did not evaluate the link between the various sources and the high nitrate levels. The objective of this study was to conduct sampling to evaluate whether chemicals other than nitrate that are associated with specific sources can be used to link the nitrate contamination in groundwater and drinking water wells to those sources. In addition, the study used several other analytical techniques (microbial source tracking, isotopic analysis, and age dating) to evaluate the contribution of various sources to high nitrate levels in drinking water wells.

To accomplish these objectives, EPA designed a three-phased study within two contiguous segments of the Yakima River Basin extending approximately 40 miles from the town of Union Gap to the Yakima County line near the town of Byron. The upper segment comprises the entire Toppenish Basin, and the lower segment comprises the northern portion of the Benton Basin. The width of the study area was defined by the width of the Toppenish and Benton Basins along the selected segment, which varies between approximately 10 and 25 miles (Figure 3).

The main focus of this report is the Phase 3 sampling. Phase 1 and Phase 2 of the study are summarized below to provide context for the Phase 3 sampling. The purpose of Phase 1 was to identify the major sources of nitrate in the study area, based on historical records. In Phase 2, the residential wells in closest proximity to the potential sources were identified, sampled, and the samples analyzed for nitrate using screening-level analytical protocols and confirmatory laboratory analysis.

Phase 3 involved using the results of Phases 1 and 2 to identify residential wells with high nitrate concentrations and locate potential upgradient nitrogen sources. Once these source areas were selected, Phase 3 involved the collection and analyses of numerous samples from the potential source areas, downgradient wells, and upgradient wells near the dairies. The following subsections provide details about each phase of the study.

A. Phase 1: Geographic Information System (GIS) Tool Development and Screening Analysis for Nitrogen Sources

The purpose of Phase 1 was to identify the major sources of nitrate in the study area based on historical records. Phase 1 included the development of a Geographic Information System (GIS) tool to organize a large amount of historical information and allow the examination of the landscape for spatial patterns in

the data. EPA used the GIS tool to identify sites to be sampled in Phases 2 and 3 of the project. The tool incorporates information from the Lower Yakima Valley about known nitrate, bacteria, and general chemistry data. It also includes information on locations of wells, land ownership, parcels with septic systems, land elevation, depth to groundwater, crop type, estimated fertilizer application rates, dairy and animal feeding operation locations, roads, and an aerial photo layer.

Phase 1 included a screening analysis to identify the potential major sources of nitrogen in Yakima County. The estimates for the different sources were used as a relative value to compare with other source estimates to assist in the study design.

The screening analysis, described below, combined information on land use with some simple calculations to estimate the amount of potential nitrogen loading from several sources that can be applied to the land. The estimates indicate three sources — livestock with dairy cattle as the largest contributor, irrigated cropland, and septic and biosoilds — account for as much as 98 percent of the nitrogen available for application to the land and potentially delivered to the aquifer (EPA 2012b). Livestock are prevalent throughout the Yakima Valley study area and accounted for about 65% of the nitrogen. Of this, dairy cows accounted for 89% of the nitrogen produced by livestock, while beef cattle were estimated at 9% and all other livestock (sheep, goats) at less than 1% each (EPA 2012b). The estimates were used as guidelines for the screening and do not account for losses of nitrogen from various biological, physical, and chemical processes. Based on this screening, EPA focused the Phase 3 sampling on three sources: dairies, irrigated cropland, and residential septic systems. Although there are other sources of nitrogen in the Lower Yakima Valley, EPA focused on the three sources believed to contribute the largest quantities of nitrogen (See Figure 6).

EPA is working to further refine these estimates and further evaluate nitrogen fate and transport in a collaborative project between EPA and the USGS. A report is due in the winter of 2012. The project focuses on better characterizing the sources of nitrogen applied to the land and the relationship between changes in nitrogen loading on the land and levels of nitrate in drinking water wells.

1. DAIRIES

As a result of economies of scale, the total number of dairy operations in the United States has been declining over time[16] while the average number of cows per dairy operation has been increasing (EPA 1998 and USDA 2010). In Yakima County, the number of dairies has decreased from 71 dairies in 1998 to 67 dairies in 2010 (WSDA 2010).

For the Phase 1 analysis, EPA used the 2008 Washington State Department of Agriculture (WSDA) estimates of the number of dairies, number of animals per dairy, and total nitrogen produced. In 2008, there were 69 dairies in Yakima County (Figure 7) registered with the WSDA (WSDA 2009). These facilities had over 130,000 animals (WSDA 2009), an average of almost 2,000 milking animal units per dairy. Modern dairies generate large quantities of animal wastes, which must be managed appropriately to prevent pollution, including pollution of surface and groundwater. Greater concentrations of animals and competition for available land have made it increasingly challenging to effectively manage animal wastes to prevent adverse impacts to public resources (Harner and others 2007).

[16] http://www.ers.usda.gov/publications

In addition to generating large quantities of manure, dairies also generate large amounts of liquid waste from flushing waste from pens and parlors to collection sites. Liquid wastes are typically stored in a series of lagoons before they are sprayed on nearby fields as fertilizer.

Dairy wastes contain key components of fertilizer, including nitrogen, phosphorous, and potassium. When used as a fertilizer, dairy wastes are often supplemented with synthetic fertilizer to meet specific nutrient needs of the crop being grown. In the lower parts of the Yakima Valley, dairies are concentrated around the cities of Sunnyside, Grandview, Mabton and Granger, although some are in more sparsely populated areas of the valley and on the Yakama Indian Reservation.

The total annual nitrogen production associated with dairies in Yakima County in 2008, without accounting for estimated losses, is approximately 36 million pounds per year. This amount was calculated by multiplying the number of dairy cows by the estimated nitrogen production rate per cow provided by the WSDA (WSDA 2009).

In addition to the animal waste lagoons, manure piles, and application fields that EPA sampled for this study, there are other potential sources on a dairy that could contribute to groundwater nitrogen loading. Other potential nitrogen sources include, but are not limited to: silage leachate, cow pens, dry wells, and ditches and pipelines between lagoon solids separators.

Large dairies employ many workers – the Cow Palace has more than 85 employees, for example.[17] Presumably the dairies in the study have substantial human waste septic systems because the area is unsewered.

Ponded water on soils mixed with manure could result in infiltration of nitrogen into the soil column. WSDA inspection reports for some dairies indicate that roof runoff is generally not directed away from areas contaminated with manure (WSDA 2012), so roof runoff could flush nitrogen into the soil column during rain or snowmelt events.

Some of the dairies in the study may be a source of inorganic nitrogen from synthetic fertilizer. WSDA inspection reports indicate the George DeRuyter & Sons Dairy, D and A Dairy, and the Liberty and Bosma Dairies use synthetic fertilizer to supplement manure applications (WSDA 2012).

2. IRRIGATED CROPLAND

Yakima County is one of the world's most fertile growing regions, with more than 240,000 acres of cropland. Agriculture is the primary economic activity in Yakima County, accounting for approximately 70 to 80 percent of land use. Most of the cropland in the area is irrigated. The major irrigation districts include Roza, Sunnyside Valley, Wapato Irrigation Project, Grandview, and Zillah. Major commodities grown in the valley include apples, alfalfa, corn for silage and grain, grapes, hops, cherries, and mint (see Figure 8).

Inorganic fertilizers can contain high amounts of nitrogen. Nitrogen application is essential to crop growth and development. Application of nutrients or water at rates greater than plant demand can result in excess nitrogen infiltrating through the soil below the root zone into the groundwater. Also, nitrogen

[17] Cow Palace website - http://cowpalacedairy.com/index.cfm?pid=inc_management

applied at appropriate rates but with high irrigation rates can move rapidly through the vadose zone, prior to full crop uptake. The amount, timing, frequency, and type of fertilizer, as well as the timing and amount of irrigation relative to the application of fertilizer and plant water demand affect the contribution to groundwater from fertilizer. Other factors such as denitrification in the soil by microorganisms, soil type, and volatilization to the atmosphere, also affect the amount of nitrate in groundwater.

EPA estimates that about 18.5 million pounds of nitrogen are applied to irrigated cropland each year in Yakima County. This estimate was derived by taking the total acreage for each crop in Yakima County in 2007 and multiplying the acreage by the Washington State University recommended average nitrogen application rate for each crop (EPA 2012b). With this methodology, EPA estimated that corn, mint and hops in Yakima County receive about 6.0, 2.1, and 1.6 million pounds of nitrogen per year respectively. Irrigated crop fields accounted for approximately 30% of the all nitrogen available for application to the land in Yakima County. These rates are general and the specific application rates and management practices by farmers could vary greatly.

3. SEPTIC SYSTEMS AND WASTEWATER

Septic systems and domestic wastewater account for about three percent of the total amount of nitrogen applied to the land in Yakima County. Domestic wastewater is managed by city wastewater treatment plants in Yakima County, but a large percentage of the rural population relies on septic systems (see Figure 9). As of 2009, there were about 22,000 septic systems registered with Yakima County (EPA 2012b). Septic systems in Yakima County are generally designed for an average number of occupants per home based on the square footage.

There are 16 permitted wastewater treatment facilities in Yakima County (EPA 2012b). As wastewater treatment facilities process and treat wastewater, they produce biosolids, which are nutrient-rich organic material. After the solids have been processed and treated, they are recycled as fertilizer and soil amendment. Biosolids land application requires a permit from Washington State Department of Ecology. About 200,000 pounds of nitrogen in biosolids are applied in Yakima County per year, which includes biosolids imported from metropolitan municipalities in Western Washington State (EPA 2012b).

An estimated 1.4 million pounds per year of potential nitrogen from human waste was calculated by multiplying the 2007 population in Yakima County (234,564) by the rate of 6 pounds of nitrogen per person per year (EPA 2012b). This approach provides an overall estimate of 1.6 million pounds per year of nitrogen from biosolids and septic systems combined.

4. CONCLUSION AND OTHER SOURCES

This screening analysis showed that about 65 percent of the nitrogen generated in Yakima County comes from livestock predominantly as dairy cattle, about 30 percent from fertilizers applied to irrigated crops, about 3 percent from septic and wastewater systems, and the rest, less than two percent, from other relatively minor sources.

These minor sources include nitrogen deposited by precipitation and non-cropland application of fertilizer to lawns, public parks, and golf courses. Application of nitrogen fertilizers was not estimated for dryland wheat crops grown in the valley because they are not irrigated and the low natural precipitation for the area limits the leaching potential of nitrate.

B. Phase 2: Identification of Wells with High Nitrate Concentrations

The objective of Phase 2 was to sample wells that were downgradient of the potential nitrogen sources identified in Phase 1, to assist in identifying sampling locations for Phase 3 sampling, and to provide residents with information on the nitrate levels in their drinking water wells. The GIS tool developed in Phase 1 was used to help identify sampling locations for Phase 2. EPA conducted the Phase 2 sampling between February 22 and March 6, 2010. Figure 10 provides a map of the locations and nitrate concentrations for the Phase 2 sampling, Table C1 in Appendix C contains a summary of the results for the compounds evaluated in Phase 2.

EPA developed a Quality Assurance Project Plan (QAPP) for Phase 2 (EPA 2010a). It identifies the data quality objectives, sampling process design, sample collection procedures, sample handling and custody requirements, analytical methods, instrument calibration, data management, and standard operating procedures for instrument calibration, shipping container preparation, and chain-of-custody process. The Center for Hispanic Health Promotion (CHHP), a local bilingual, bicultural organization affiliated with the Fred Hutchinson Cancer Research Center, was contracted to assist in recruiting residences for sampling, scheduling, and Spanish interpretation assistance.

A series of public meetings, newspaper articles, and radio announcements notified the community of EPA's Phase 2 work. Samples were collected by two-person teams trained for the project. Sample teams verified consent for access from the homeowner, collected a global positioning system (GPS) location at the well, and completed a data collection form developed by EPA. Each sampling team maintained a field logbook to document sampling activities. Water quality parameters were measured in the field using a Horiba multi-parameter probe for each well.

The parameters measured included dissolved oxygen, oxidation/reduction potential, total dissolved solids, pH, and temperature. The sampling team also used nitrate colorimetric test strips (Hach® test strips) as a field screening tool to provide an indication of whether the water exceeded the MCL of 10 mg/L for nitrate. The Hach® test strips measure nitrate concentrations in increments of 0, 1, 2, 5, 10, 20, and 50 mg/L**.** If the Hach® test strip indicated the water may exceed the MCL (10 mg/L), samples were collected for analysis by EPA's Manchester Environmental Laboratory ("EPA's Manchester Laboratory").

Samples submitted to the laboratory were also analyzed for enumeration and quantification of total coliform using EPA's mobile microbiology laboratory. If total coliform bacteria were present, the samples were also analyzed for *Escherichia coli* ***(****E. coli)* and fecal coliform bacteria.

During the two weeks EPA was in the field, 331 homes were visited and all were screened for nitrate levels using the Hach® test strips. EPA's Manchester Laboratory received 189 samples for analysis. Of these 189 samples, 102 were analyzed for nitrate and chloride, two were analyzed for nitrate and nitrite, and 123 were analyzed for total Kjeldahl nitrogen (TKN). Samples for 67 of those homes, or about 20 percent, were found to exceed the MCL of 10 mg/L for nitrate (Figure 10).

The percentage of homes with nitrate levels in wells above the MCL in this study were higher than the 12 percent from earlier studies because the homes sampled in Phase 2 were selected based on their proximity to likely sources. This method of selection would be expected to bias the results compared with a study where the sampling locations were selected randomly. If potential upgradient sources such as dairy lagoons, dairy application fields, irrigated crop fields, or septic systems were likely sources of nitrate to

the aquifer, this would help explain the higher percentage of residences with nitrate levels over the MCL. Another possible explanation for the higher percentages of water wells with nitrate levels above the MCL in this study is that the previous studies were completed several years ago and the areas with nitrate levels above the MCL may have increased in size.

Eight wells, or 2 percent, were found to have fecal coliform bacterial contamination or contamination with *E. coli.* This result is less than the 20 percent frequency found in past studies.

Residents were informed of the nitrate results from the Hach® test strips immediately. Residents of all of the homes with nitrate levels greater than 10 mg/L or with bacterial contamination were provided with written laboratory results.

The Phase 2 sampling was informative in several ways. The results confirmed that nitrate concentrations in many residential drinking water wells were above the EPA drinking water standard of 10 mg/L and provided information to the residents on the levels of nitrate in their wells. In addition, the Phase 2 results were used to identify the Phase 3 sampling locations.

C. Phase 3: Investigating Source Contributions to High Nitrate Concentrations in Drinking Water Wells

The objective of Phase 3 was to investigate the contribution of various sources from nearby land uses to high nitrate levels found in water wells using a wide array of sampling and analysis techniques. The water wells shown in Figure 10 with the highest nitrate concentrations were selected for more extensive Phase 3 sampling and analyses.

Drinking water samples were collected from existing wells. No new wells were installed for this study. Available information on well depths is summarized in Appendix A1.

EPA evaluated three types of sources (dairies, irrigated cropland, and residential septic system) (See Figure 11). The three source types and sampling areas are shown in Table 1. Table 1 also illustrates how the study design varied, depending on the waste source type (dairy, irrigated cropland, or septic systems). EPA also collected and analyzed representative residential drinking water wells upgradient of the dairies. No drinking water wells upgradient of the crop fields or septic systems were sampled.

In general:

- Investigation of each of the two dairy areas (Haak Dairy and the Dairy Cluster) included sampling a number of downgradient wells, dairy animal waste lagoons, dairy manure piles, and dairy application fields. In addition one upgradient well was sampled in each dairy area. The well and waste samples were analyzed for many different chemicals and microbes using several analytical techniques. The data for the downgradient wells were compared to the data for the upgradient wells and the various waste sources to show the relative nitrate contamination and to determine if any of the different compounds could be used to identify specific sources.[18]

[18] Note that during Phase 2, for both the Haak Dairy and the Dairy Cluster focus areas, nitrate data was collected from additional downgradient residential drinking water wells and, for the Dairy Cluster, nitrate data was collected from two additional upgradient drinking water wells (see Appendix C1 for results from sample locations WW-22103 and WW-22085).

Table 1: Overview of the Study Design to Investigate Potential Sources of Nitrate in Water Wells Near Dairies, Irrigated Cropland, and Septic Systems

Source Type	Sampling Area	Upgradient Well Sample	Supply Well Sample	Potential Sources of Nitrate	Downgradient Well Samples	Study Design[c,d]
Dairies	Haak Dairy	WW-01	WW-02	Lagoons (LG-01 to LG-03) Manure Piles (SO-01) Application Fields (SO-02)	WW-03 to WW-05	Compare chemicals and microbiology in upgradient wells and sources with downgradient wells. Conduct isotopic analyses for water wells and lagoons and age dating for water wells.
	Dairy Cluster	WW-06[a]	WW-07, WW-08, and WW-09	Lagoons (LG-04 to LG-15) Manure Piles (SO-03, SO-05, SO-07, and SO-09) Application Fields[b] (SO-04, SO-06, SO-08, and SO-10)	WW-10 to WW-17	
Irrigated Croplands	Schilperoort Farm	NA	NA	SO-11 (Mint)	WW-23	Compare chemicals in downgradient wells with soil samples from associated crop fields.
	Havilah Farm	NA	NA	SO-12 (Mint)	WW-24	
	Wheeler Farm	NA	NA	SO-13 (Corn)	WW-25	
	Sunny Dene Ranch	NA	NA	SO-14 (Corn)	WW-28	
	Golden Gate Hops	NA	NA	SO-15 (Hops)	WW-26	
	Golden Gate Hops	NA	NA	SO-16 (Hops)	WW-27	
Septic Systems	Mabton	NA	NA	Septic Systems	WW-21	Compare chemicals in water wells with influent from 3 wastewater treatment plants (Zillah, Mabton, and Toppenish).
	Harrah	NA	NA	Septic Systems	WW-19	
	Sunnyside	NA	NA	Septic Systems	WW-20 and WW-22	

[a]As noted above, in footnote 2 of the text, EPA collected samples from other wells located upgradient of the Dairy Cluster which were also below the MCL for nitrate during Phase 2. That data is included in this report in Table C1 in Appendix C (sample location WW-22103 and WW-22085).

[b]Thirty soil samples per application field or crop field were collected at a depth of 1 inch and composited to obtain a representative sample.

[c]Two additional residential wells, WW-18 and WW-30, were sampled during this study, but were not included in the original study design or listed in this table. The results for these two wells are documented in Section IX.E of this report.

[d]See Table C2 in Appendix C and Table C ES-2 for a description of the analytes for each source.

NA – not applicable.

- The investigation of six irrigated crop fields (two hops, two mint, and two corn) included sampling six downgradient wells, one downgradient of each crop field. A soil sample was collected from each of the six irrigated crop fields. The chemicals detected in each downgradient well were compared with the chemicals detected in the corresponding soil sample from each of the six crop fields.
- The investigation of the three septic waste areas included sampling residential wells downgradient from septic systems. The chemicals detected in the downgradient wells were compared to samples collected from the influent to wastewater treatment plants (WWTPs) located in Toppenish, Mabton and Zillah. These WWTP influent samples were selected to be representative of the types of chemicals that could be released from residential septic systems, while recognizing that these WWTPs also may receive commercial and industrial waste streams.

The water well, dairy lagoon, dairy manure pile, dairy application field, crop field, and WWTP influent samples were evaluated for several general water chemistry parameters, microbiology parameters, and organic chemicals. Not all samples were evaluated for all of the general chemistry, microbiology parameters, or organic chemicals. The water well, dairy lagoons, and WWTP influent samples were evaluated using isotopic analysis and the water well samples were evaluated using age dating techniques (See Section VII).

1. PHASE 3 SAMPLING LOCATIONS

EPA used the Phase 1 GIS tool, Phase 2 sampling results, and a set of selection criteria to identify 63 sampling locations for Phase 3. (See Figure 11 for the location for each of the sampling sites). Table C2 in Appendix C provides the sample location, sample location type, description of the sample medium, and a summary of analytes at each location. For more information on the sampling locations and sampling procedures see the Quality Assurance Project Plan for the Yakima Basin Nitrate Study, Phase 3 – Comprehensive Analytical Source Tracer Sampling, April 2010 (EPA 2010b).

Criteria for Selection of Dairies and Associated Sampling Locations

EPA collected samples at several dairies. Dairies were selected based on data from Phases 1 and 2 of the project, considering the following criteria:

- High concentration of animals per acre.
- Indication of over-application of nutrients to fields associated with the dairies based on information contained in WSDA inspection reports. (WSDA 2012).
- Relatively consistent direction of groundwater flow from season to season.
- Minimal upgradient nitrate sources to the extent possible.
- Existence of private drinking water wells along the downgradient side, or sides, of the dairy.
- History of nitrate levels above the MCL in downgradient drinking water wells.

Samples were collected from dairy animal waste lagoons, dairy manure piles, dairy application fields, and supply wells associated with the dairies. In general, one sample was collected at the influent to the lagoon system, and two samples were collected at the outlet from the lagoon system. The dairy manure pile

samples were collected on site at each dairy. The dairy application field samples were collected where lagoon waste had recently been applied. Residential drinking water wells upgradient and downgradient of the dairies were also sampled.

Selection of upgradient and downgradient wells for this study was based on groundwater flow direction and gradient data compiled by USGS. According to USGS, the generalized direction of groundwater flow in the study area in both the shallow sedimentary hydrogeologic unit and the deeper basalts is toward the Yakima River (USGS 2009). Flow directions can vary locally due to canal/lateral leakage, irrigation, drains, streams, pumpage, variations in recharge, spatially varying hydraulic characteristics, and topographic setting (USGS 2009). Groundwater flow directions were determined by USGS by measuring depth to water and reflecting these localized influences at the time it was measured. In this study, EPA sampled residential drinking water from a tap and depth to water was not measured.

Criteria for Selection of Irrigated Cropland Areas and Associated Sampling Locations

Soil samples were collected from two fields each of corn, hops, and mint.[19] These crops were selected because they require significant quantities of nitrogen to produce the large amounts of plant biomass for yield in contrast with other crops such as tree fruit. Thirty shallow soil samples per field were collected at a depth of 1 inch and composited to obtain a representative soil sample. One well situated downgradient of each crop field was selected for sampling. The criteria used for selection of the six crop fields were as follows:

- History of high fertilizer application rates, use of agricultural chemicals, and irrigation water applied for crop growth.
- Relatively consistent direction of groundwater flow from season to season.
- Minimal upgradient nitrate sources.
- History of nitrate levels above the MCL in downgradient drinking water wells.

Criteria for Selection of Residential Septic System Areas and Associated Sampling Locations

Samples were collected from four private drinking water wells that had high nitrate concentrations in Phase 2 and were located downgradient of areas with a high density of residential septic systems. Additionally, samples were collected from the influent to three small wastewater treatment plants in the Lower Yakima Valley (Zillah, Mabton, and Toppenish) to serve as a surrogate for septic system influent and to characterize compounds found in rural septic systems. The criteria used to select the water well sampling locations in the residential septic system areas included:

- High density of homes not served by sanitary sewers.
- Relatively consistent direction of groundwater flow from season to season.
- Minimal upgradient nitrate sources other than septic.

[19] The owners of the six crop fields sampled are indicated in Table 1.

VII. PHASE 3: COMPOUNDS AND ANALYTICAL TECHNIQUES

EPA analyzed for nearly 200 chemicals and used several analytical techniques to investigate the source of high levels of nitrate in water wells. The chemical analyses and analytical techniques were grouped as follows: general chemistry; microbial data; organic compounds; isotopic analysis; and age dating. The data for each of the analytical techniques are evaluated independently in an effort to identify the specific sources of the high nitrate concentrations found in residential drinking water wells. Table 2 summarizes the chemicals analyzed and the techniques used to analyze the samples collected from the water wells, dairy sources (dairy lagoons, dairy manure piles, and dairy application fields), wastewater treatment plants and irrigated crop fields.

This section describes the analyses that make up each of the five groups, the rationale for performing each of the analyses, and the issues or challenges associated with specific analyses and techniques. The analytical results are summarized in Appendix C and a discussion of the results is provided in Section IX.

A. General Chemistry

The study evaluated four areas of general chemistry: nitrate and other forms of nitrogen; major ions; minor and trace inorganic elements; and perchlorate. Each is discussed below.

1. NITRATE AND OTHER FORMS OF NITROGEN

Water well samples were analyzed for nitrate, nitrate plus nitrite, ammonia, and TKN. TKN is the total concentration of organic nitrogen and ammonia. TKN was analyzed to ensure all major forms of nitrogen were quantified. Samples from the dairy lagoons and WWTP influent were analyzed for nitrate plus nitrite, ammonia, and TKN. Nitrate alone was not analyzed in the lagoon and WWTP influent samples because nitrate would not be expected to be present in these media because of the anoxic (lack of oxygen) conditions.

In addition, the total nitrogen concentration for each sample was calculated by summing the concentrations of nitrate, nitrite, and TKN. These values were used to compare total nitrogen concentrations in upgradient and downgradient water wells with total nitrogen concentrations in sources, such as dairy lagoons, dairy manure piles, and dairy application fields, located between the up- and down-gradient wells, and to evaluate whether patterns exist. The results for the water wells, dairy lagoons, and WWTP influent samples are summarized in Table C3 in Appendix C.

Dairy manure piles, dairy application field, and crop field samples were analyzed for extractable nitrate (reported as Nitrate-N/Nitrite), extractable ammonia (reported as Ammonium-N), and total nitrogen by combustion (reported as Total Nitrogen/Solid). These analyses were conducted to provide an indication of the total nitrogen concentration in the dairy manure piles, dairy application field, and crop field samples. The results for the dairy manure piles, dairy application field samples, and crop field samples are included in Table C4 in Appendix C. Nitrate was analyzed at three different laboratories using different methods. Cascade Analytical Laboratory in Union Gap analyzed the water wells samples for nitrate using EPA Method 300.0 because this method is specified for evaluating nitrate concentrations in drinking water. Method 300.0 provides for measurement of nitrate alone. Method 300.0 requires the

Table 2: Summary of the Chemical Groups and Media Included in Phase 3 of the Study

Compound or Analytical Technique (Number of Compounds Analyzed)	Water Wells	Dairy Lagoons	Dairy Manure Piles	Dairy Application Fields	WWTP Influent[c]	Crop Soils
General Chemistry						
Nitrate (1)	X		X	X		X
Other Nitrogen Forms[a]	X	X	X	X	X	X
Major Ions (9)	X	X			X	
Trace Elements (12)	X	X			X	
Perchlorate (1)	X					
Microbiology						
Bacteria (3)	X	X			X	
Microbial Source Tracking[b]	X	X			X	
Organic compounds						
Pesticides (50)	X	X[d]	X	X	X[d]	X
Trace Organics (69)	X	X			X	
Pharmaceuticals (31)	X	X	X	X	X	X
Hormones (20)	X	X	X	X	X	X
Analytical Techniques						
Isotopic Analysis (2)	X	X			X	
Age Dating (NA)	X					

[a]Other nitrogen forms for water wells and lagoons include ammonia, TKN, and nitrate plus nitrite. Other forms of nitrogen for manure piles, dairy application fields, and crop samples include extractable nitrate, extractable ammonia, and total nitrogen by combustion.

[b] Microbial source tracking was conducted only if there was an indication of fecal contamination detected in the sample.

[c]Majority of influent from households but contribution from businesses and industry also expected.

[d]Because of matrix interference, results for pesticide analysis for lagoon and wastewater treatment influent samples were not useable.

X – the compound or analytical technique was analyzed.

NA – not applicable

sample to be analyzed within 48 hours after it is collected; therefore, samples were shipped to Cascade Analytical Laboratory because of its proximity to the study area.

EPA's Manchester Laboratory analyzed the water well samples for nitrate using Method 353.2. Method 353.2 measures nitrate plus nitrite. Finally, the University of Nebraska – Lincoln Water Sciences Laboratory ("UNL" or "UNL Laboratory"), also analyzed the water well samples for nitrate as part of the isotopic analysis. The UNL Laboratory used *Distillation and Determination of Ammonium and Nitrate Nitrogen in Water for Nitrogen Isotope Analysis* (SOP# Analyte-DISTN15-004) for their analysis.

Table C5 in Appendix C provides a summary of the nitrate concentrations reported by each of the three laboratories for the water wells sampled in Phase 3. The results for the nitrate analysis are similar among the three laboratories, with one exception: sample WW-18 where there was good agreement between two of the three results.

2. MAJOR IONS

All water wells, dairy lagoons, and WWTP influent samples were analyzed for the major ions by EPA's Manchester Laboratory. The major ions were not analyzed in the soil and manure samples because, in general, the purpose for analyzing the major ions is to track the chemical evolution of migrating groundwater.

An ion is an electrically charged species consisting of a single atom or a group of atoms. It is formed when a neutral atom or group of atoms either gains or loses electrons. The major ions evaluated included calcium, chloride, fluoride, iron, magnesium, nitrate, potassium, sodium, and sulfate. The results for the major ions are included in Table C6 in Appendix C.

Different ions have different chemistries and transport mechanisms. For example, chloride does not generally sorb to particles or participate in reactions with the aquifer material. Other ions, such as potassium and sodium, are much more likely to react with minerals and sorb to aquifer materials.

For this study, the results for major ions in the various samples were compared to determine whether a spatial pattern was observed in the concentrations. If the concentrations of specific ions in the downgradient wells are higher than in the upgradient wells, and those same ions are abundant in a specific source then the source is a likely contributor to those higher levels. For example, if chloride is detected at high levels in a dairy lagoon and the concentrations of chloride in a water well downgradient of the dairy lagoon are higher than in a well upgradient of the dairy lagoon, it indicates the dairy lagoon is a likely source of chloride to the downgradient well.

3. MINOR AND TRACE INORGANIC ELEMENTS

EPA's Manchester Laboratory analyzed the samples from all water wells, dairy lagoons, and WWTP influents for minor and trace inorganic elements. Twelve minor and trace inorganic elements were evaluated: arsenic, barium, bromide, cadmium, chromium, copper, lead, manganese, mercury, selenium, silver, and zinc. Minor and trace inorganic elements were not analyzed in the samples from crop fields or manure piles. The results for the minor and trace inorganic elements are included in Table C6 in Appendix C.

The trace inorganic elements were included in this study to evaluate the potential influence of organic carbon sources. The mobility of certain metals is controlled by oxidation/reduction potential (how oxygen rich the waters are), which in turn is controlled by the amount of organic carbon consumed in microbial reactions. For example, if the metal concentrations in downgradient water wells are elevated compared with the upgradient wells, it may indicate the influence of an organic carbon source such as a dairy lagoon.

4. PERCHLORATE

All wells were tested for perchlorate and analyzed by the EPA's Robert S. Kerr Environmental Research Center in Ada, Oklahoma ("EPA's Ada Laboratory" or "Ada"). The results for perchlorate are in Table C7 in Appendix C. Perchlorate is the most highly oxidized form of chlorine and tends to accumulate in caliche-associated soils in arid regions such as Eastern Washington and Oregon (Rao and others 2007). In this study, it was used as an indicator for potential naturally occurring nitrate.

There is a very slight, but steady, deposition of nitrate and perchlorate from the atmosphere. Much of the deposition starts as aerosol salt particles released from combustion in transportation or power generation or carried off the oceans as aerosols or dust particles from deserts by winds (Prospero and Lamb 2003). In this region, the National Atmospheric Deposition Program (http://nadp.sws.uiuc.edu/) calculates aerial deposition of atmospherically derived nitrate at approximately 0.9 pound per acre per year. Perchlorate accumulates at much lower rates but has not been studied to the same extent, so data are lacking.

This accumulation of nitrate and perchlorate has been occurring since the end of the last glacial period, approximately 10,000 years ago. In areas of higher rainfall, both these compounds are sufficiently soluble to be carried into the subsurface and potentially into groundwater. However, these compounds can build up in the shallow subsurface with the calcium carbonate that forms the cement-like caliche layer in arid regions such as the Lower Yakima Valley. The same conditions that would wash the nitrate out of a caliche soil horizon (the first application of irrigation water to a new field converted from sage habitat) would flush out perchlorate as well.

B. Microbiology

All water wells, dairy lagoons, and WWTP influent samples were analyzed for either total coliform, fecal coliform, or *E. coli* as an indicator of fecal contamination. The results for microbiology are in Table C8 in Appendix C. EPA's mobile microbiology laboratory from its Manchester Laboratory or Cascade Analytical Laboratory in Union Gap conducted the analysis. MST was performed for nine of the dairy lagoons and all three of the WWTP influent samples because they tested positive for fecal contamination. Six of the lagoons were not tested for MST, even though they tested positive for fecal contamination, because of limited resources. MST was not conducted for the Phase 3 water well samples because fecal coliform was not detected.

MST is a means of identifying the source of the fecal contamination in a water sample. The method used in this study is genotypic and is used to detect the presence of host-specific Bacteroides species shed in the fecal material of humans or ruminants. This method allows a presence or absence reporting format for these two sources. A common way of referring to the host-specific genetic identifier for each of these species is a "biomarker."

Because the MST method used in this case is limited to presence or absence reporting only for human and ruminant sources, the data cannot be used to: (1) identify the quantity or proportional levels of contamination from either source; (2) identify specific sources other than human or ruminant; or (3) differentiate between the various kinds of ruminants — cattle, goats, sheep, deer, or elk.

However, the data can be used to: (1) identify the frequency of identification of either of the sources from a particular sampling site if more than one set of samples is collected from the same site; (2) identify human or ruminant source contamination; and (3) confirm that recent fecal contamination has occurred.

C. Organic Compounds

The study looked at four groups of organic compounds: pesticides; trace organics; pharmaceuticals; and hormones. Organic compounds are subject to a number of factors that affect their fate and transport properties and would cause them to travel differently from nitrate in groundwater. Organic molecules are much more likely to sorb to materials in the aquifer, which could retard their migration compared to nitrate. In addition, organic compounds are subject to microbial degradation, which would reduce their concentration in groundwater over time.

1. PESTICIDES

Fifty pesticides were analyzed in water wells, dairy lagoons, WWTP influents, dairy manure piles, dairy application field samples, and crop soil samples by EPA's Manchester Laboratory. The term "pesticide" refers to insecticides, herbicides, fungicides, and various other substances used to control pests. The pesticide analysis conducted as part of this investigation included insecticides and herbicides. The results for the pesticides are included in Table C9 in Appendix C.

The pesticides selected for analysis were those that USGS reported had been used in the Yakima Valley and are considered mobile in groundwater, persistent, or both (Nakagaki and Wolock 2005). Many of the pesticides are used on specific crops and during specific times of the year. This pattern of usage can be an advantage, as it can assist to identify the specific crop where the pesticide was applied. At the same time, it is possible that a particular pesticide, though used in the area, was not applied before the time of sample collection and may not have been detected in the soil samples collected by EPA.

EPA's Manchester Laboratory reported that the sample matrices provided significant interferences that made pesticide analysis difficult for dairy lagoons and WWTP influent samples. Because of this problem, the pesticide concentrations could not be quantified in the dairy lagoons or WWTP influent samples. The laboratory attempted to develop an extraction and cleanup procedure for the dairy lagoon and WWTP sample matrix; however, a procedure to resolve the matrix interference could not be developed within the maximum holding time specified for these samples. The maximum sample holding times would have been exceeded by the time the laboratory could have developed and tested an effective and reliable procedure. Therefore, the pesticide results for the dairy lagoon and WWTP samples are considered unusable for all purposes.

2. TRACE ORGANICS

Each water well, dairy lagoon, and WWTP influent sample was tested for 69 trace organic compounds by the USGS National Water Quality Laboratory in Denver ("USGS NWQ Laboratory"). The trace organics

were not analyzed in soil or manure samples because the USGS NWQ Laboratory was not equipped for this type of analysis and the methods for extraction of such samples are complex. The results for the trace organics and a description of their main use are included in Table C10 in Appendix C.

The USGS developed a method for analyzing a large number of trace organics because USGS and other researchers had found them in domestic and industrial wastewater (Zaugg and others 2006) as well as groundwater and surface waters (Kolpin and others 2002, Barnes and others 2008). EPA believed the trace organics would help to differentiate water wells affected by septic systems (humans) from water wells influenced by other sources such as dairy lagoons or irrigated cropland. The compounds analyzed include many that can be associated with human usage, including caffeine, bisphenol A, cholesterol, menthol, phenol, various flame retardants, acetophenone (fragrance in detergent), benzophenone (fixative for perfumes), camphor (flavor, oxidant), isoborneol (fragrance in perfume), and many others.

3. WASTEWATER AND VETERINARY PHARMACEUTICALS

The sample from each water well, dairy lagoon, WWTP influent, dairy manure pile, dairy application field, and crop sample was analyzed for 14 wastewater pharmaceuticals (Table 3). UNL performed the analysis. The results are included in Table C11 in Appendix C.

Table 3: Wastewater Pharmaceuticals Analyzed and a Description of their Uses

Compound Name[a]	Description
Acetaminophen	Pain reliever (Tylenol)
Amphetamine	Psychostimulant (Dexedrine)
Azithromycin	Antibiotics (Zithromax)
Caffeine	Stimulant
Carbamazepine	Anticonvulsant
Cotinine	Metabolite of nicotine
DEET	Insect repellent
Diphenhydramine	Antihistamine
Ibuprofen	Pain reliever
Methamphetamine	Psychostimulant
Naproxen	Pain reliever (Aleve)
Paraxanthine	Stimulant (metabolite of caffeine)
Thiabendazole	Parasiticide (mintezol)
Triclosan	Antibacterial

[a]The University of Nebraska – Lincoln Water Sciences Laboratory (UNL) conducted the analyses for these compounds.

The group is identified as "wastewater pharmaceuticals" because they are generally used by people for therapeutic reasons and have been detected in municipal wastewater (Ternes and others 2004), surface waters (Kolpin and others 2002), groundwater (Barnes and others 2008), and drinking water (Benotti and others 2009). Many of the compounds are for over-the-counter use (for example, acetaminophen and ibuprofen) and are ingested, but a few are applied topically (DEET and triclosan). Two of the compounds may be used in other animals (thiabendazole and DEET).

People typically excrete 50 to 90 percent of the active ingredients in ingested drugs, either as unmetabolized pharmaceuticals or as metabolites (McGovern and McDonald 2003). These excreted compounds can enter a municipal WWTP or a septic system. Detection of these compounds in water wells may provide evidence that septic systems are a likely source of nitrate. If detected in the influent to the WWTPs, it can establish whether these compounds are being excreted by humans and ending up in municipal sewage waste. If the compounds are detected in the WWTP influent, they can be compared with detected compounds in water wells to evaluate whether septic systems may contribute to the presence of these compounds in well water.

In addition, the sample from each water well, dairy lagoon, WWTP influent, dairy manure pile, dairy application field, and crop sample was analyzed for 17 additional pharmaceuticals and classified as "veterinary pharmaceuticals" for this study. Table 4 lists the compounds and the current U.S. Food and Drug Administration (FDA) approved uses (FDA 2011a and FDA 2011b). Many of the pharmaceuticals shown in Table 4 do not require a veterinarian's prescription and are available for over-the-counter purchase (FDA 2011a and FDA 2011b).[20] The majority of the over-the-counter pharmaceuticals are included in animal feed. The UNL Laboratory also conducted these analyses. The results are included in Table C12 in Appendix C.

Detections of the compounds in Table 4 in water wells would provide evidence that dairy cattle or other animals are a likely source of those compounds. For example, if monensin is detected in water wells, then it is coming from a source other than people (monensin is not approved for use in humans). If the compounds are detected in dairy lagoons, dairy manure piles, or dairy application fields, it is a good indication that the dairy is using the compound.

The UNL Laboratory analyzed the compounds in Table 4 because they are used in livestock production at therapeutic doses to treat and prevent disease and at sub-therapeutic doses as prophylactics and growth promoters (Meyer 2004) and have been found at low levels in various environmental media: groundwater (Barnes and others 2008 and Kummerer 2009); surface water (Koplin and others 2002; Christina and others 2003; and Kummerer, 2009); and wastewater treatment facilities (Ternes and others 2004; and Lubliner and others 2010). More specifically, several of the compounds have been found in dairy lagoons (Watanabe and others 2008 and Watanabe and others 2010); soil and surface samples from dairies (Watanabe and others 2010); private wells nearby a beef cattle operation (Batt and others 2006); and in groundwater underlying swine and beef cattle facilities (Bartlet-Hunt and others 2011). Some of the compounds in Table 4 (such as tetracycline and erythromycin) are also used by people (Kummerer 2009).

The U.S. Department of Agriculture's (USDA's) National Animal Health Monitoring System conducted a survey to evaluate the use of antibiotics in dairy operations for disease prevention, disease treatment, and growth promotion in pre-weaned heifers, weaned heifers, and mature cows (USDA 2008). The survey represented 17 of the nation's major dairy states (Washington was included) and represented about 82 percent of the U.S. dairy cows. The results indicate that the majority of dairy operations use antibiotics to

[20] Compounds that can be obtained over-the-counter include chlortetracycline; erythromycin; lincomycin; monensin; ractopamine; sulfadimethoxine; sulfamethazine; sulfathiazole; tetracycline; tiamulin; trenbolone; tylosin; and virginiamycin.

treat for diarrhea, digestive problems, respiratory problems, mastitis, reproductive disorders, and lameness.

Table 4: Veterinary Pharmaceuticals Analyzed and their FDA Approved Uses

Compound Name[a]	Current FDA Approved Use[b]
Chlortetracycline (total)	Cattle (beef, dairy), poultry, swine, and sheep
Erythromycin	Cattle (beef, dairy) and humans
Lincomycin	Swine, poultry, and humans
Monensin	Cattle (beef, dairy), and poultry
Oxytetracycline	Cattle (beef, dairy), poultry, sheep, and humans
Ractopamine	Cattle (beef), swine, and poultry.
Sulfachloropyridazine	Cattle (beef), swine, and sheep
Sulfadimethoxine	Cattle (beef, dairy), and poultry
Sulfamerazine	Poultry
Sulfamethazine	Cattle (beef, dairy), poultry, and swine
Sulfamethizole	Dogs and cats
Sulfamethoxazole	Humans
Sulfathiazole	Swine
Tetracycline	Cattle (beef, dairy), poultry, sheep, swine, and humans
Tiamulin	Swine
Tylosin	Cattle (beef, dairy), poultry, and swine
Virginiamycin	Swine and poultry

[a]The University of Nebraska – Lincoln Water Sciences Laboratory (UNL) conducted the analyses for these compounds.

[b]Approved as of November 2011.

EPA requested information from the dairies on the use of pharmaceuticals in their operations to identify which of the pharmaceuticals might be used by the dairies in this study. The dairies declined to provide this information to EPA; therefore, there is no specific information from the dairies on their use of these compounds.

4. HORMONES

Each water well, lagoon, and WWTP influent sample was analyzed for five estrogen hormones (17-α-estradiol, 17-α-ethynyl-estradiol; 17-β-estradiol; estriol; and estrone) by EPA's Robert S. Kerr Environmental Research Center in Ada, Oklahoma. The results for these hormones are in Table C13 in Appendix C.

In addition, each water well, dairy lagoon, WWTP influent, dairy manure pile, dairy application field sample, and crop sample was tested for 20 estrogen, androgen, and progestin hormones by the UNL Laboratory, including the five estrogen hormones analyzed by EPA's Ada Laboratory. The results for these analytes are in Table C14 in Appendix C. Table 5 shows all the compounds

evaluated and their natural source or general use. The table also provides information on the FDA approved uses for certain of the analytes as of November 1, 2011 (FDA 2011a and FDA 2011b).

Table 5: Hormonally Active Compounds Analyzed and Descriptions of their Origins and Current FDA Approved Uses

Compound Name[a]	Description (Current FDA Approved Use)
Analyzed at both EPA's Ada Laboratory and the UNL Laboratory	
17-β-Estradiol	Estrogen, natural female sex hormone - many animals
17-α-Estradiol	Estrogen, natural isomer of 17- β-estradiol - many animals
Estriol	Estrogen, natural female sex hormone - many animals
Estrone	Estrogen, natural female sex hormone - many animals
17-α-Ethynyl Estradiol	Estrogen, synthetic analogue of estradiol used for birth control (human)
Analyzed at the UNL Laboratory Only	
11-Keto Testosterone	Androgen, oxidized metabolite of natural testosterone - many animals
17-α-Hydroxyprogesterone	Inactive metabolite of natural progesterone - many animals
4-Androstenedione	Androgen, natural precursor in producing testosterone and estrogens - many animals
Androsterone	Androgen, natural metabolite of testosterone - many animals
Epitestosterone	Inactive isomer of natural testosterone - many animals
Progesterone	Progestin, natural female sex hormone - many animals; also used as a growth promoter (beef cattle)
Testosterone	Androgen, natural male sex hormone - many animals
17-α-trenbolone	Androgen, synthetic growth promoter (beef cattle)
17-β-trenbolone	Androgen, synthetic growth promoter (beef cattle)
Androstadienedione	Androgen, metabolite of natural progesterone and testosterone - many animals; also used as precursor for producing synthetic boldenone, a growth promoter (horse)
α-Zearalanol	Estrogen, naturally produced by plant fungi and found in pasture animals - many animals; also produced synthetically as a growth promoter (beef cattle and sheep)
α-Zearalenol	Estrogen, precursor of natural α-zearalanol- many animals
β-Zearalanol	Estrogen, isomer of α-zearalanol naturally produced by plant fungi and found in pasture animals - many animals
β-Zearalenol	Estrogen, precursor of natural β-zearalanol- many animals
Melengesterol Acetate	Progestin, synthetic growth promoter (beef cattle)

[a]EPA's Robert S. Kerr Environmental Research Center (EPA's Ada Laboratory) and the University of Nebraska – Lincoln Water Sciences Laboratory (UNL Laboratory) both conducted the analyses for these compounds.

Analytes were selected both as a result of laboratory method development showing success at analysis and because of the frequent detections in the environment. Most of these hormones are produced naturally by humans and other animals (Williams and Stancel, 1996; Wilson, 1996; Lange and others, 2002;

Johnson and others, 2006), and some are even produced by plants or fungi (Carson and others, 2008). Many of these hormones can be used as pharmaceuticals in human and veterinary clinical practices (Zheng and others 2008).

Many of the compounds have been detected at low levels in various environmental media or sources, including surface waters (Kolpin and others 2002); dairy lagoons (Kolodziej and others 2004; Arnon and others 2008; Hutchins and others 2007, and Zheng and others 2008); groundwater associated with dairies (Kolodziej and others 2004, Arnon and others 2008); and manure at dairy facilities (Raman and others 2004).

Some of the synthetic hormones analyzed could be indicative of specific animal sources. For example, 17-α-ethynyl-estradiol is a synthetic analogue of 17-α-estradiol and is used in hormonal contraception exclusively in humans. This compound would not be expected to be found in dairy lagoons, unless the lagoons also receive human waste, but could be found in WWTP influent and septic systems.

Another example includes the synthetic growth hormones trenbolone and melengesterol acetate, which are used to promote growth in beef cattle. These compounds are not approved for use in dairy cows, and would not be expected to be detected in dairy lagoons, dairy manure piles, or dairy application fields. If these compounds are detected in water wells, it is an indication that there is a source other than dairy cows or people.

In addition to these compounds, there are some hormones that might indicate a specific animal source, but are not necessarily conclusive. For example, 17-α-estradiol is predominantly produced by dairy cows and could be useful for source tracking (Hanselman and others, 2003), but it is also found in smaller amounts in other animals and in fact can be produced during biotransformation of other natural hormones (Czajka and Londry, 2006). Another example is α-zearalanol and its isomers and precursors; this is produced synthetically as a growth promoter for sheep and beef cattle, but is also produced naturally by plant fungi and can be found in pasture-grazed animals not subject to hormone treatment (Erasmuson and others, 1994).

D. Isotopic Analysis

Samples from all the water wells, dairy lagoons, and WWTPs were submitted to the UNL Laboratory for isotopic analysis. The results of the isotopic analyses are presented in Table C15 in Appendix C. A detailed discussion regarding the interpretation of the isotopic data can be found in Appendix D.

Stable isotopes of the various nitrogen species that make up dissolved inorganic nitrogen (nitrate, nitrite, and ammonium) in water can indicate the general source, or combination of sources, or dominant processes acting on nitrogen in groundwater (Kendall 1998; Kendall and Aravena 1999; Michener and Lajtha 2007). Stable isotopes of nitrate and ammonium can explain the possible origin and process that formed the dissolved inorganic nitrogen in water wells. The ability to attribute nitrate in water wells to specific sources using isotopic analysis maybe a useful supplement to other methods used to identify possible sources.

The interpretation of isotopic data is complex. Multiple studies have shown that different nitrate sources can have overlapping isotopic composition (Kendall and others 2007). In many cases, it is not possible to distinguish the different nitrate sources using isotopic analysis alone if the isotopic ranges overlap.

Extensive sampling within a specific study area is needed to allow different nitrate sources to be identified with more confidence.

Isotopes are forms of the same element that have a different number of neutrons and thus a different mass. As an example, the atomic weight of nitrogen is 14.0067 because the most common isotope of nitrogen is the form with seven neutrons and seven protons and a mass number of 14, written as ^{14}N. ^{14}N makes up 99.636 percent of the total nitrogen in the atmosphere and is referred to as the "light isotope" because it has a lower atomic weight than ^{15}N. Nitrogen 15 consists of seven protons and eight neutrons and, written as ^{15}N, makes up the rest of the total nitrogen in the atmosphere at 0.364 percent and is referred to as the "heavy" isotope."

Isotopic values are reported as the ratio of the heavy isotope (in this case, ^{15}N) to the light isotope (in this case, ^{14}N) in the sample compared with that ratio in a chosen standard. For nitrogen, the standard is the pool of nitrogen in the earth's atmosphere, referred to as the atmospheric standard. Nitrogen isotopic composition is expressed in terms of "delta ^{15}N," which is written as $\delta^{15}N$ and is expressed as parts per thousand differences from the atmospheric standard stated as, "per mil" or written as ‰.

$$\delta^{15}N\ (‰) = \frac{(^{15}N/^{14}N)_{sample} - (^{15}N/^{14}N)_{standard}}{(^{15}N/^{14}N)_{standard}} * 1000$$

$\delta^{15}N$ will be positive (for example, +6.1‰) and therefore heavier if there is more of the ^{15}N compared with the atmospheric standard in the sample. $\delta^{15}N$ will be negative (for example, -0.2‰), or lighter, if there is less of ^{15}N in the sample compared with the atmospheric standard. The $\delta^{15}N$ values are reported as either $\delta^{15}N\text{-}NO_3$ (for nitrate) or $\delta^{15}N\text{-}NH_4$ (for ammonium).

Isotopes of oxygen (^{18}O) have also been used to provide information on the source of nitrate in a sample. The standard for ^{18}O is "Standard Mean Ocean Water," or SMOW. The $\delta^{18}O$ of O_2 gas in the atmosphere is 23.5‰, which is heavier than the $\delta\ ^{18}O\text{-}NO_3$ typically found in nitrate sources without atmospheric influence. Nitrate derived from atmospheric deposition has much heavier $\delta^{18}O\text{-}NO_3$ values in comparison to other nitrate sources of 60‰ to 95‰ (Kendall and others 2007). The ^{18}O values are reported as $\delta\ ^{18}O\text{-}NO_3$ (for nitrate).

E. Age Dating

Several methods are available to measure the age of groundwater in a well, meaning the amount of time that has elapsed between the initial infiltration of the water into the ground and when it was sampled in the well. The measured age of the water may be useful in determining whether the nitrate in water wells is associated with either past or current practices. For this study, EPA used a method involving the analysis of sulfur hexafluoride (SF_6). SF_6 is used for age dating because it has been steadily increasing in the atmosphere as it is released by human activities. To determine the age of the water, the laboratory measures the concentration of SF_6 in the water sample and compares it to measured atmospheric concentrations of SF_6 over time.

SF_6 is a liquid at room temperature and can occur naturally in igneous formations. Industrial production began in the early 1950s. Significant production of SF_6 began in the 1960s for use in high-voltage electrical switches as a replacement for polychlorinated biphenyls (PCBs). SF_6 is extremely stable, with

an estimated atmospheric lifetime of 800 years (Morris and others 1995) to 3,200 years (Ravishankara and others 1993). As more of it is produced, more of it is found in the atmosphere. SF_6 is very persistent in the atmosphere, so the concentration has been steadily increasing. The SF_6 age dating method used in this study can estimate the age of water up to about 40 years, since approximately 1970.

All water wells samples were analyzed for SF_6. The analysis was completed by the USGS laboratory in Reston, Virginia ("USGS Reston Laboratory"). The USGS Reston Laboratory was selected because this laboratory has developed a method that had been used successfully by USGS in Washington State. This analysis is not conducted by commercial laboratories.

In addition to the SF_6 analysis, five gas studies were conducted. These studies involved filling containers with water for the analysis of nitrogen and argon gas to measure the temperature and elevation of the recharge zone for the groundwater. These data are used to correct the SF_6 measurement for excess nitrogen, which can be dissolved when groundwater elevations fluctuate rapidly. It also provides a means to determine if nitrogen gas has been added to the sample from denitrifying bacteria breaking down nitrate in an anoxic setting. None of the EPA samples showed evidence of denitrification based on measured nitrogen to argon ratios. A summary of the results for the age dating is in Table C16 in Appendix C.

SF_6 values were not reported for WW-01, WW-11, WW-12, WW-23, WW-27, and WW-28 (Table C16 in Appendix C). Values were not reported for these samples because the concentration of SF_6 in the groundwater exceeded the highest expected concentration based on average atmospheric concentrations of SF_6. These samples may indicate areas where localized human-caused releases of SF_6 occurred. For example, there could have been an accidental release during servicing of high-voltage equipment or the intentional introduction of SF_6 into water for localized fate and transport studies or for tracing leaking pipes. Based on USGS SF_6 age dating research, the high values of SF_6 observed in certain samples are likely from anthropogenic sources and not related to background levels seen in some volcanic regions.

VIII. QUALITY ASSURANCE AND QUALITY CONTROL

As discussed previously, the project was implemented in three phases. In Phase 1, a GIS screening application was developed and used to identify potential sample locations and sites in the Lower Yakima Valley for Phase 2 sampling. Phase 1 also developed estimates of the nitrogen available for application to the land from different sources. Phase 2 and Phase 3 involved sampling and analysis as described in Sections V, VI, and VII. A discussion of the QA/QC procedures followed in Phase 2 and Phase 3 and a summary of the data validation process conducted by EPA QA chemists are presented in Appendix E. All of the chemical analyses conducted for the Phase 3 study met project data quality goals and criteria and are useable for all purposes, except as noted in Appendix E.

IX. ANALYTICAL RESULTS AND DISCUSSION

The following subsections present the analytical results for the Phase 3 sampling and are organized by the type and location of the source area. The three types of source areas include: dairies; irrigated cropland; and residential septic systems. In addition, one well was sampled that was not related to a specific dairy or crop field (WW-18) and one well was sampled that was not included in the QAPP (WW-30). The locations sampled are illustrated on Figure 11 and include the following:

- Haak Dairy.
- Dairy Cluster (composed of a group of dairies in close proximity).
- Irrigated and fertilized crop fields (three locations: Mabton [three separate crops], Harrah [one crop], and Sunnyside [two separate crops]).
- Septic Systems (four downgradient wells: one in Mabton; one in Harrah; and two in Sunnyside; plus influent from the WWTPs located in Zillah, Mabton, and Toppenish).
- Two residential drinking water wells (WW-18 and WW-30) not associated with a specific dairy or irrigated cropland.

The analytical data for each of the five locations listed above are presented according to the analytical groups described in Section VII: general chemistry; microbiology; organic chemicals; isotopic analyses, and age dating. Each section provides a summary of all of the results for each location.

A data usability review and validation independent of the laboratories were conducted by EPA and are discussed in Appendix E. Data usability is indicated in the data summary tables by inclusion of data qualifiers. The data qualifiers are defined in the footnotes of the data summary tables and further explained in Appendix E. A discussion of data bias, where it could be determined, also is included in Appendix E.

A. R&M Haak Dairy

The R&M Haak Dairy (Haak Dairy) is located in an agricultural area north of the Yakima River, about four miles north of the community of Sunnyside. It is in the Benton groundwater basin, which includes the communities of Sunnyside, Grandview, Satus, Kiona, Prosser, Mabton, and Richland. A ditch runs from north to south through the Haak Dairy. Cow pens, a milking parlor, and three animal waste lagoons lie west of the ditch. There are several large structures where cows are kept. East of the ditch, a center-pivot irrigation system is installed on a large application field that the dairy uses to apply animal waste.

EPA selected this dairy for this study because it generally met the criteria identified in the study plan (see Section VI.C.1). Specifically, the Haak Dairy has: a high concentration of animals per acre; WSDA inspectors noted in their reports for the Haak Dairy that elevated levels of nitrogen were detected in its application fields in the past (WSDA 2012); the Haak Dairy is located near the northern edge of cultivated land use and in a location with relatively few upgradient potential sources of nitrogen; and drinking water wells downgradient of the Haak Dairy showed nitrate levels above the MCL.

NUMBERS OF ANIMALS AND AMOUNT OF WASTE GENERATED

In the past 30 years, the average U.S. dairy herd has increased from 29 to 139 head per farm (USDA 2009). While this is a sizable increase, the dairies in this study are considerably larger. In general, the WSDA is prohibited by state law from providing information to the public identifying the number of animals; the volume of livestock nutrients generated; the number of acres covered by a Nutrient Management Plan (NMP) or used for land application of livestock nutrients; quantities of livestock nutrients transferred to other persons; and crop yields in plans, records, and reports obtained by the state and local agencies from dairies, Animal Feeding Operations (AFOs) or Concentrated Animal Feeding Operations (CAFOs). They can provide some of this information in ranges (WSDA 1996 and WSDA 2010). Table 6 provides information on the number of animals and the amount of dairy waste generated

at the Haak Dairy before and after factoring in estimated losses during storage from volatilization or denitrification.

Table 6: Haak Dairy – Approximate Numbers of Dairy Cattle, Annual Manure Production, and Annual Nitrogen Production

Mature Dairy Cattle	Heifers/ Calves	Annual Manure Production[a] (tons)	Annual Nitrogen Production as Excreted[b] (tons)	Annual Nitrogen After 35% Losses Occur[c] (tons)
700 to 1,699	300 to 399	20,573 – 52,220	129 – 323	84 – 210

[a]Annual manure production is calculated using the following formula: [((# of milking cows)*1.4*108) + ((# of dry cows)*1.4*51) + ((# of heifers)*0.97*56) + ((# of calves *0.33*83)]*365/2000 (WSDA 2010)

[b]Nitrogen production is calculated using the following formula: [((# of milking cows)*1.4*.71) + ((# of dry cows)*1.4*.3) + ((# of heifers)*0.97*.27) + ((# of calves *0.33*.42)]*365/2000 (WSDA 2010)

[c]Losses due to volatilization or denitrification during storage are estimated at 35%. This does not include application losses.

A farm with 2500 dairy cattle is similar in waste load to a city of 411,000 people (EPA 2004). A difference lies in the fact that human waste is treated before discharge into the environment, but animal waste is either not treated at all or minimally treated before discharge into the environment (EPA 2004). Applying this estimate to the range of 700 to 1,699 mature dairy cattle, the Haak Dairy produces an amount of waste similar to a community of 115,000 to 278,000 people.[21] This estimate is based only upon the numbers of mature dairy cattle. It does not include the additional waste load of heifers and calves. For comparison, the human population of Yakima County in 2010 was 243,231.[22]

Sizable amounts of nitrogen, a component of manure, are generated by the Haak Dairy. Nitrogen production can be roughly estimated by applying the ranges of the numbers of animals to formulas used by the WSDA to estimate manure and nitrogen production. The WSDA estimates that during storage at a typical dairy, about 35 percent of the nitrogen in dairy waste is "lost" through the process of volatilization or denitrification (WSDA 2010). The formula does not assume any leakage into the subsoils from the lagoons or other structures or conveyances. If the remaining nitrogen is not taken up by crops or is transported off site to another location, it can migrate to groundwater after being mobilized by irrigation water or precipitation.

WASTE MANAGEMENT

The Haak Dairy uses a variety of animal waste storage methods, including a solids separator, a lagoon system, and dry stacking. The surface area of the Haak Dairy's lagoons is approximately 269,000 square feet, which is equivalent to about 5 football fields (assumes a football field is 57,600 square feet). EPA estimated the surface area of the lagoon system using aerial photographs. The storage capacity of the Haak Dairy's lagoon systems was derived from WSDA inspection reports (WSDA 2012). The Haak

[21] Calculations: 411,000 persons divided by 2500 dairy cows equals 164 persons per cow. 700 cows times 164 persons per cow equals 115,000 persons. 1.699 cows times 164 persons per cow equals 278,000 persons.

[22] U.S. Census Bureau: http://quickfacts.census.gov/qfd/states/53/53077.html

Dairy's lagoon system storage capacity is 9,400,000 gallons which is equivalent to the volume of about 14 Olympic-size swimming pools (assumes the capacity of an Olympic-size swimming pool is 660,000 gallons).

NRCS Washington recommends avoiding the use of "agricultural waste storage ponds" (lagoons), unless no reasonable alternative exists, at locations like the Haak Dairy where there is an aquifer that serves as a domestic water supply (NRCS Washington 2004). If no reasonable alternative exists, consideration should be given to the following: 1) a clay liner designed in accordance with procedures of Agricultural Waste Management Field Handbook Appendix 10D ("NRCS Appendix 10D") with a thickness and coefficient of permeability so that specific discharge is less than 1×10^{-6} cm/sec; 2) a flexible membrane liner over a clay liner; 3) a geosynthetic clay liner (GCL) flexible membrane liner; or 4) a concrete liner designed in accordance with slab on grade criteria for fabricated structures requiring water tightness."

EPA estimated the seepage from lagoons for the Haak Dairy using unit seepage rates from NRCS Appendix 10D and from a field study by Ham and DeSutter (Ham 2002). Lagoon design should consider unit seepage rates in addition to other factors such as state and local requirements and site-specific conditions (e.g., groundwater flow and depth to groundwater) (NRCS 2008). State regulations for specific discharge range from about 500 gallons per acre per day (1/56 inch or 0.45 mm per day) to about 6,800 gallons per acre per day (1/4 inch or 6.35 mm per day) (NRCS 2008). Applying a unit seepage rate of 500 gallons per acre per day to the surface area of the Haak Dairy lagoons equates to an approximate seepage volume of 1,080,000 gallons per year, the equivalent of about 1.6 volumes of an Olympic-size swimming pool annually (Table 7).

Table 7: Haak Dairy – Lagoon System Surface Area, Storage Capacity, and Estimated Leakage Rate

Approximate Lagoon System Liquid Surface Area (square feet)	Lagoon System Storage Capacity (gallons)[23]	Estimated Lagoon System Leakage, Based on Unit Seepage Rate of 500 Gallons per Acre per Day (gallons per year)	Estimated Range of Lagoon System Leakage, Based on Ham Seepage Rate Range (gallons per year)
269,000	9,400,000	1,080,000	482,000 to 5,873,000

Leakage rates of lagoon systems with compacted soil liners were estimated in the field by Ham and DeSutter (Ham 2002). The leakage rates they derived were based on field measurements of animal waste lagoons lined with compacted soil liners with an average hydraulic conductivity of 1.8×10^{-7} centimeters per second. Based on field observations, they concluded that lined dairy lagoons leak at a rate of 0.2 to 2.4 millimeters per day (Ham 2002). Applying the Ham and DeSutter rates to the surface area of the Haak Dairy lagoons, leakage rates can be estimated and are presented in Table 7.

[23] Lagoon systems are generally designed to hold about one third of a dairy's annual liquid waste generation (the amount that would be generated over a four month time period).

Based on the liner infiltration rates developed by the Ham and DeSutter study (Ham 2002), a lined lagoon system of the size of the Haak Dairy's would release approximately 482,000 to 5,873,000 gallons per year into the underlying soils and could threaten groundwater. This amount is the equivalent of about 1 to 9 volumes of Olympic-size swimming pools annually.

The seepage rate of 0.45 mm per day falls within the Ham and DeSutter range of 0.2 to 2.4 mm per day. Leakage rates for the Haak Dairy lagoons would likely be greater than the above estimates if the lagoons are unlined. If the lagoons are lined with a plastic liner, the actual leakage rates could be lower, although plastic liners can be punctured during construction and lagoon maintenance, especially during periodic dredging activities.

EPA requested information from the Haak Dairy about how its lagoons were constructed, but the Dairy declined to provide this information. EPA has asked Yakima County, the WSDA, the Washington Department of Ecology, and the NRCS if any of the Haak lagoons have engineered liners, but none of the agencies could affirm that they do. Many states require lagoons to meet permeability requirements. However, EPA is unaware of any state or local requirements that would compel dairies in Yakima County to construct lagoons to any specific level of permeability.

Utilization rates of the lagoon systems (the percent of lagoon capacity occupied by liquid waste) at the time of the inspection are also provided in the inspection reports. Lagoon utilization rates tend to vary throughout the year. One purpose of the lagoons is to provide storage of liquid dairy waste during the winter months. Such storage is needed to avoid applying dairy wastes to fields during the winter, which can result in the contamination of groundwater if there are no plants growing to take up the nutrients in the waste. Dairy operators generally try to pump out their lagoons toward the end of the growing season so they have sufficient lagoon capacity to store waste through the winter months. Lagoon utilization rates noted in recent inspection reports for the Haak Dairy are summarized in Table 8. A dashed line indicates there was no entry in the report for that particular data element.

SURFACE SOILS

Surface soils in Yakima County have been characterized and mapped by the U.S. NRCS (NRCS 2012). A soil report has been developed for the Haak Dairy (EPA 2012a) and is summarized in Appendix B. All of the surface soils underlying the Haak Dairy have a "well drained" classification, which means water moves readily through the soil.

Most of the surface soils on which the Haak Dairy operates have a high saturated hydraulic conductivity. The percentage of surface soils with a "high" saturated hydraulic conductivity at the Haak Dairy is 82 percent while the percent of surface soils with a "low" saturated hydraulic conductivity is 18 percent. The permeability of the surface soils at the Haak Dairy is more fully described in Appendix B.

Table 8: Haak Dairy – Washington State Department of Agriculture Inspection Dates and Reported Values for Lagoon Capacity

Date of Inspection	Lagoon Capacity (gallons)	Number of Days of Lagoon Capacity[24]	Percent of Lagoon Capacity Utilized at Time of Inspection
3/25/2010	9,400,000	4 months plus	75%
12/18/2008	-----	-----	60%
7/7/2008	9,400,000	4 months plus	80%
9/5/2006	9,400,000	120 days	100%

Animal waste applied to crop fields can be a significant source of nitrogen loading to the soil, groundwater and surface water. Applying large quantities of animal wastes on highly permeable surface soil (i.e., soil with a high hydraulic conductivity) increases the risk of groundwater contamination because water from irrigation or precipitation can readily infiltrate the soil and carry nitrogen past the root zone before it can be taken up by plants (EPA 2004). "Agronomic" nitrogen application rates are typically based on soil types and crop yield goals. However, agronomic nitrogen application rates are not necessarily protective of drinking water. Even with agronomic application rates, mismanagement of irrigation water can move nitrogen through the vadose zone.

APPLICATION FIELDS

The Haak Dairy applies animal wastes as fertilizer onto between 121 and 300 acres of application fields that it owns or leases (WSDA 2010). The WSDA does not disclose exact acreages of the application fields to the public. Corn and triticale (a cross of wheat and rye) are grown in these fields. These crops have relatively high nitrogen needs and can be used as feed. At the time of inspection, WSDA inspectors documented in inspection reports that animal wastes were applied to six fields using a spreader "honey wagon", a sprinkler irrigation system, and a dry spreader (WSDA 2012). Because the Haak Dairy did not provide the information EPA requested about its operations, it is unknown how much manure or liquid dairy lagoon waste the Haak Dairy applies to its fields. However, WSDA inspectors documented that the Haak Dairy measured and recorded elevated levels of nitrogen on some of the its application fields (WSDA 2012). State records also indicate the Haak Dairy exported some of its animal waste to other landowners.

Figure 11 and Figure 12 show the Phase 3 sample locations associated with the Haak Dairy. The sampling locations include:

[24] "Number of Days of Lagoon Capacity" is an estimate of the maximum number of days a lagoon system could accept liquid dairy waste under normal operating conditions without having to be pumped out. It is intended to assess whether a lagoon system is sufficiently large enough to hold liquid waste generated by the dairy throughout the winter months, without having to be pumped out to the waste application fields when there are no crops growing that could take up the nutrients in the waste. It assumes the lagoon system was completely pumped out at the beginning of the time period.

- One residential drinking water well upgradient of the dairy (WW-01);
- One dairy supply well (WW-02);
- One dairy manure pile located on the dairy (SO-01);
- Two dairy lagoons from which three samples were collected (LG-01, LG-02, and LG-03). Lagoon samples LG-02 and LG-03 are from the same lagoon;
- One dairy application field sample (SO-02) and;
- Three downgradient residential drinking water wells (WW-03, WW-04, and WW-05).

1. HAAK DAIRY: GENERAL CHEMISTRY

The four types of general chemistry data collected at the Haak Dairy were: nitrate and other forms of nitrogen; major ions; minor ions and trace inorganic elements; and perchlorate. The results for each of these analyses are discussed below.

Haak Dairy: Nitrate and Other Forms of Nitrogen

Five water well samples, three dairy lagoon samples, one dairy manure pile sample, and one dairy application field sample were analyzed for several forms of nitrogen. The water wells and lagoons were analyzed for nitrate, nitrate plus nitrite, ammonia or ammonium (if in an aqueous solution), and TKN. The dairy manure pile and the dairy application field samples that were receiving dairy waste were analyzed for extractable nitrate-N (Nitrate-N Solid), extractable ammonia-N (Ammonia-N Solid), and total nitrogen by combustion (Total Nitrogen Solid).

In addition, the total nitrogen was calculated for each sample. Total nitrogen is the sum of nitrate, nitrite, and TKN. Using total nitrogen values allows a comparison between different locations. These calculated values are presented as "Calculated Total Nitrogen" in Table 9. The manure sample, SO-01, contained only 22 percent solids and was analyzed for TKN rather than total nitrogen by combustion. For SO-02, the total nitrogen equals the nitrate plus the TKN value. The total nitrogen for all other solid samples equals the nitrogen by combustion result.

Organic forms of nitrogen were not detected in the five water wells and therefore the total nitrogen values in Table 9 for the water wells are the sum of the nitrate plus nitrite concentrations. Nitrate and nitrite were not detected in the lagoon samples LG-01 or LG-03 and therefore the total nitrogen values in Table 9 for the two dairy lagoons are reflected by the TKN values. There is an increase in concentrations of total nitrogen between the upgradient well and the downgradient wells (Figure 12 and Table 9).

The dairy lagoons, dairy manure piles, and dairy application fields at the Haak Dairy are located between the upgradient and downgradient wells sampled and are a likely source of the increased nitrogen levels in the downgradient residential water wells. A WSDA inspection report indicates the Haak Dairy has used inorganic fertilizer on its application fields, in addition to animal wastes (WSDA 2012). In addition, the alkalinity concentrations are greater in the downgradient wells compared to the upgradient well, with the highest concentrations in the dairy lagoons.

Available information about the construction and depth of WW-03 and WW-04, the downgradient wells, suggest they are completed in the alluvial aquifer at depths of 95 feet and 88 feet. Information about the upgradient well, WW-01, is limited. Information on the construction of the dairy lagoons (if they are lined, and if so, with what material) would be useful to determine the extent to which they may be

contributing to the increase in nitrogen concentrations. EPA formally requested this information from the Haak Dairy, but the information was not provided.

Table 9: Haak Dairy – Distribution of Total Nitrogen in Wells, Lagoons, a Manure Pile, and an Application Field.

Sample Location	Nitrate as N (ppm)	Nitrate + Nitrite as N (ppm)	Ammonia as N (ppm)	TKN as N (ppm)	Calculated Total Nitrogen (ppm)
Water Wells and Lagoons					
WW-01: Upgradient Well	0.38	0.39	ND	ND	0.39
WW-02: Dairy Supply Well	3.1	3.4	ND	ND	3.4

Dairy Manure Pile				
Sample Location	**Ammonia-N Solid (ppm)**	**Nitrate-N Solid (ppm)**	**Total Nitrogen Solid (ppm)**	**Total Nitrogen (ppm)**
SO-01: Dairy Manure Pile	10,100	ND	29,700 (as TKN)	29,700

Dairy Application Field				
Sample Location	**Ammonium as N (ppm)**	**Nitrate + Nitrite as N (ppm)**	**Total Nitrogen Solid (ppm)**	**Total Nitrogen (ppm)**
SO-02: Dairy Application Field	4.6	71.7	2760	2760

NA – Not analyzed.

ND – Not detected.

J – the analyte was positively identified, but the associated numerical value is an estimate.

Haak Dairy: Major Ions

Five wells and three dairy lagoon samples were analyzed for the major ions. Figure 13 shows the concentrations of six major ions (calcium, chloride, magnesium, potassium, sodium, and sulfate) in the upgradient well, the dairy lagoons, and the downgradient wells. The concentrations of these six ions all have higher concentrations in the downgradient wells and one or more of the lagoons than the upgradient well. Alkalinity shows a similar pattern.

The difference in concentrations from the upgradient well to downgradient wells ranges from up to a 3-fold increase for potassium; an 8–fold increase for magnesium; more than a 10-fold increase for calcium and sodium; more than a 30-fold increase for chloride and more than a 65-fold increase for sulfate.

Chloride is considered a conservatively transported ion (Freeze and Cherry 1979; Gooddy and others 2002), meaning that it typically flows with the groundwater unchanged and is unlikely to participate in reactions or be electrically attracted to minerals making up the aquifer matrix. Based on the observed concentrations, chloride and other ions are being introduced to the aquifer between the upgradient and downgradient wells at the Haak Dairy. One explanation for the observed increase in these major ions is that the dairy lagoons are introducing these ions to the groundwater. As with total nitrogen, this indicates that the Haak Dairy is a likely source of the major ions in the three downgradient residential drinking water wells at the Haak Dairy.

Haak Dairy: Minor and Trace Inorganic Elements

Five water well and three dairy lagoon samples were analyzed for minor and trace inorganic elements. Two metals, barium and zinc, which may be used at dairies, were detected in both the water wells and dairy lagoons (Table 10). There is an increase in the concentrations from the upgradient to the downgradient wells for both barium and zinc, with the highest concentrations in the lagoons. Other metals (chromium, copper, iron, and manganese) were detected in dairy lagoons, but were not found in the water wells. The dairy manure pile and dairy application field samples were not analyzed for minor or trace inorganic elements.

Table 10: Haak Dairy – Concentrations of Barium and Zinc in Wells and Lagoons

Location	Barium (µg/L)	Zinc (µg/L)
WW-01 – Upgradient Well	13.5	Not detected
WW-02 – Dairy Supply Well	32.7	5.4
LG-01 – Dairy lagoon	297	1790
LG-02 – Dairy lagoon	931	5410
LG-03 – Dairy lagoon	907	5260
WW-03 – Downgradient Well	135	21
WW-04 – Downgradient Well	178	12
WW-05 – Downgradient Well	164	15

Haak Dairy: Perchlorate

Perchlorate was analyzed only in the water well samples (Table C7 in Appendix C). The concentrations ranged from 0.14 micrograms per liter (µg/L) (WW-01) to 1.96 µg/L (WW-03). The results for the perchlorate analysis are evaluated together with the isotopic data because perchlorate was used as an indicator of potential accumulation of atmospherically derived nitrate associated with caliche soils (see Appendix D). Perchlorate was not evaluated in the dairy lagoon system because it is not expected to persist in the anoxic environment of a dairy lagoon.

2. HAAK DAIRY: MICROBIOLOGY

The water well samples were analyzed for total coliform and *E. coli* (Table C8 in Appendix C). Only one well (WW-04) had a detectable level of total coliform, but *E. coli* was not detected. MST was not completed for this well because *E. coli*, a form of fecal coliform, was not detected.

Samples from the three dairy lagoons were analyzed for fecal coliform. As would be expected, high concentrations of fecal coliform were found in the dairy lagoons. MST was performed on the samples from the three dairy lagoons. One of the samples (LG-01) indicated a ruminant source, while two of the samples (LG-02 and LG-03) indicated both human and ruminant sources. Lagoon samples LG-02 and LG-03 are collocated, so similar results for these samples are expected; however, it is unknown why the MST results for this dairy lagoon indicate human sources.

3. HAAK DAIRY: ORGANIC COMPOUNDS

The organic compounds evaluated included: pesticides; trace organics; pharmaceuticals; and hormones.

Haak Dairy: Pesticides

All the samples collected at the Haak Dairy were analyzed for pesticides; however, the laboratory was unable to quantify pesticide concentrations in the lagoon samples because of matrix interference (Table C9 in Appendix C).

Atrazine was the only pesticide detected in the water wells. Atrazine also was detected in one of the dairy application field samples. The concentrations of atrazine detected in the water wells and dairy application field sample at the Haak Dairy are summarized in Table 11. None of the water well samples exceeded the MCL for atrazine of 3.0 µg/L.

Table 11: Haak Dairy – Concentrations of Atrazine in Wells, a Manure Pile, and an Application Field

Location	Atrazine
WW-01 – Upgradient Well	0.015 (J) µg/L
WW-02 – Dairy Supply Well	0.041 (J) µg/L
WW-03 – Downgradient Well	Not Detected
WW-04 – Downgradient Well	0.015 (J) µg/L
WW-05 – Downgradient Well	0.11 (J) µg/L
SO-01 – Dairy Manure Pile	Not Detected
SO-02 – Dairy Application Field	1.1 (J) µg/kg

J – the analyte was positively identified, but the associated numerical value is an estimate.

Atrazine is an herbicide commonly used on corn fields and is frequently detected in groundwater beneath both urban and agricultural land uses (Barbash and others 1999). Both grain and silage corn is significant in dairy and other cattle livestock operations. The detection of atrazine at a higher concentration in one of the downgradient wells compared with the upgradient well indicates that there likely is a source from a

crop field associated with the Haak Dairy; however, the presence of atrazine in the upgradient well indicates that the Haak Dairy is not the only source.

Three pesticides (Dicamba, Dacthal-DCPA, and 2,4-D) were found in the dairy manure pile sample from the Haak Dairy (SO-01). In addition to atrazine, five other compounds were detected in the dairy application field sample collected adjacent to the Haak Dairy (SO-02): 4-nitrophenol; pentachlorophenol; endosulfan sulfate; chlorpyrifos ethyl; and diuron. The dairy application field was historically planted with corn and triticale.

Haak Dairy: Trace Organics

Trace organic analysis was performed on the water well and lagoon samples, but not on the manure or soil samples collected at the Haak Dairy (Table C10 in Appendix C). One compound, bis-(2-ethylhexyl) phthalate, (DEHP) was detected in WW-01 (upgradient well) at a concentration of 2.66 µg/L and in WW-03 (downgradient well) at a concentration of 5.26 µg/L. The MCL for DEHP is 6.0 µg/L. Phthalates, such as DEHP, are compounds used in the manufacture of plastics to decrease the brittleness of containers and other objects. They are increasingly ubiquitous in the environment (EPA 2011).

Other trace organics were detected in the three Haak Dairy lagoons but not detected in any of the downgradient wells (Table C10 in Appendix C). Compounds found in all three dairy lagoons included fecal indicators (such as 3-beta-coprostanol and 3-methyl-1h-indole); plant sterols (for example, beta-sitosterol, beta-stigmastanol, and cholesterol); p-creosol; 4-nonylphenol-monoethoxylate; and phenol.

Haak Dairy: Pharmaceuticals

Analyses were conducted for two suites of pharmaceutical chemicals: wastewater pharmaceuticals and veterinary pharmaceuticals. The wastewater pharmaceuticals analyzed in this study are generally used by humans. Veterinary pharmaceuticals are used in veterinary practice and many can also be used to treat people.

There were no wastewater pharmaceuticals detected in the water well, dairy manure pile, or dairy application field samples. Thiabendzadole, which is used to treat worm infections in both livestock and humans and can be used as a pesticide (Mayo Clinic 2011), was detected in one dairy lagoon (LG-01) sample. DEET, an insect repellent, was detected in one dairy lagoon (LG-03) sample. A summary of the wastewater pharmaceutical data is provided in Table C11 in Appendix C.

Three veterinary pharmaceuticals (tetracycline, chlortetracycline, and monensin) were detected in one or more water wells, dairy lagoon, dairy application field or dairy manure pile sample. Detected concentrations for these three compounds are summarized in Table 12. Several additional veterinary compounds were detected in the dairy lagoons: LG-01 (eight compounds); LG-02 (nine compounds), and LG-03 (six compounds). Several compounds were also detected in the manure sample (SO-01: four compounds) and dairy application field sample (SO-02: five compounds). A summary of the veterinary pharmaceutical data is provided in Table C12 in Appendix C.

Tetracycline was detected in two of the downgradient wells (WW-03 and WW-04) and in the dairy lagoon, dairy manure pile, and dairy application field samples. The detections in all the dairy supply

sources provides a good indication that tetracycline is used at the Haak Dairy. These data indicate that the Haak Dairy is a likely source of tetracycline in the two downgradient residential water wells.

Table 12: Haak Dairy – Concentrations of Pharmaceuticals in Wells, Lagoons, a Manure Pile, and an Application Field

Sample Location	Tetracycline	Chlortetracycline	Monensin
WW-01 – Upgradient Well	ND	ND	0.027 µg/L
WW-02 – Dairy Supply Well	ND	ND	ND
LG-01 – Dairy Lagoon	1.96 (J) µg/L	R	45.0 (J) µg/L
LG-02 – Dairy Lagoon	5.83 (J) µg/L	0.067 (J) µg/L	1086 (J) µg/L
LG-03 – Dairy Lagoon	2.88 (J) µg/L	R	420 (J) µg/L
SO-01 –Dairy Manure Pile	178 µg/kg	ND	441 µg/kg
SO-02 – Dairy Application Field	26.9 µg/kg	45.6 µg/kg	2.9 µg/kg
WW-03 – Downgradient Well	0.041 (J) µg/L	ND	0.028 µg/L
WW-04 – Downgradient Well	0.075 (J) µg/L	0.049 µg/L	0.023 µg/L
WW-05 – Downgradient Well	ND	ND	0.022 µg/L

J – the compound was positively identified, but the associated numerical value is an estimate.

ND – Not detected

R – the data is unusable for all purposes because of analytical problems with the sample.

Monensin was detected in the upgradient well (WW-01) and all three of the downgradient wells (WW-03, WW-04, and WW-05). Monensin was also detected in the Haak dairy lagoons, manure sample, and application field sample. The detection of monensin in the upgradient well indicates there is an upgradient source of this compound. The high concentrations of monensin seen in the Haak Dairy lagoon samples, manure pile, and application field sample indicate that it is used at the Haak Dairy. The data indicate that the Haak Dairy is a possible source of monensin in the three downgradient residential drinking water wells. Given the presence of monensin in the upgradient well, another source of monensin is likely.

Haak Dairy: Hormones

Hormone analysis was conducted by two laboratories. EPA's Ada Laboratory, analyzed water well and dairy lagoon samples for five hormones (Table C13 in Appendix C). Solid samples (soil and manure) were not analyzed by EPA's Ada Laboratory because the laboratory specializes in liquid samples and had not developed solid extraction techniques at the time of the study. Hormone analysis also was conducted by the UNL Laboratory. The UNL Laboratory analyzed both the liquid and solid samples, including the samples collected from water wells, dairy lagoons, dairy manure piles, and dairy application fields. The UNL's Laboratory hormone analysis includes 20 compounds (Table C14 in Appendix C), including the five hormones analyzed by EPA's Ada Laboratory.

EPA's Ada Laboratory did not detect hormones in any of the water well samples. EPA's Ada Laboratory detected 17-β-estradiol, 17-α-estradiol, and estrone in the three lagoons at the Haak Dairy, but did not detect 17-α-ethynyl-estradiol or estriol in the dairy lagoons.

The UNL Laboratory did not detect any of the five hormones analyzed by EPA's Ada Laboratory in water well samples. The UNL Laboratory detected testosterone in samples from all five wells and epitestosterone in one well (WW-04). Testosterone also was detected in LG-01 (See Table 13). Epistesterone was not detected in any of the dairy sources. Four hormones were detected in all three dairy lagoons (17-α-estradiol, α-zearalanol, and progesterone) and two hormones were detected in both the dairy manure pile and dairy application field samples (4-androstenedione, 17-α-estradiol) (Table C14 in Appendix C). The concentration of testosterone in the upgradient well (WW-01) was greater than in the downgradient wells (WW-03 to WW-05), although the highest concentrations were in LG-01.

Table 13: Haak Dairy – Concentrations of Testosterone in Wells, Lagoons, a Manure Pile, and an Application Field

Location	Testosterone
WW-01 – Upgradient Well	21 ng/L
WW-02 – Dairy Supply Well	16 ng/L
LG-01 – Dairy Lagoon	32 ng/L
LG-02 – Dairy Lagoon	Not Detected
LG-03 – Dairy Lagoon	Not Detected
SO-01 – Dairy Manure Sample	Not Detected
SO-02 – Dairy Application Field Sample	Not Detected
WW-03 – Downgradient Well	9 ng/L
WW-04 – Downgradient Well	12 ng/L
WW-05 – Downgradient Well	7 ng/L

ng/L – Nanograms per liter

4. HAAK DAIRY: ISOTOPIC ANALYSES

As discussed in Section VII.D, isotopic analysis can indicate the general source, or combination of sources, or dominant processes acting on nitrogen in groundwater (Kendall 1998; Michener and Lajtha 2007). Stable isotopes of nitrate and ammonium can explain the possible origin and process that formed the nitrate in water wells. The ability to attribute nitrate in water wells to specific sources using isotopic analysis may be a useful supplement to other methods used to determine possible sources.

The three main sources of nitrate evaluated for their contribution to water wells using isotopic analysis were animal waste, synthetic fertilizer, and atmospheric deposition. Animal waste can include both human and non-human animal waste. Based on the isotopic results from this study, and the scientific literature, a $\delta^{15}N\text{-}NO_3$ value greater than 8.4‰ indicate that the likely dominant source of nitrate in water wells is animal waste. A $\delta^{15}N\text{-}NO_3$ value less than 2.0‰ indicate that the likely dominant source of nitrate in water wells is synthetic fertilizer. Values of $\delta^{15}N\text{-}NO_3$ between 2.0‰ and 8.4‰ indicate that the nitrate source is animal waste, synthetic fertilizer, or a combination of the two. $\delta^{18}O\text{-}NO_3$ values of 20‰ or higher were interpreted

as evidence of some atmospheric contribution. The rationale for the selection of these values is in Appendix D. Table 14 below provides the specific results for the five water wells.

Table 14: Haak Dairy – Concentration of Nitrate in Wells, Isotopic Signatures, and the Interpreted Dominant Source of the Nitrate

Well Number	Nitrate-N (mg/L)[a]	$\delta^{15}N\text{-}NO_3$ (‰)	$\delta^{18}O\text{-}NO_3$ (‰)	Interpreted Dominant Source(s)[b]
WW-01	0.2	NM	NM	NM
WW-02	3.0	2.7	15	Indeterminate
WW-03	34	2.3	29	Fertilizer and/or Animal Waste[c] with Some Atmospheric Contribution
WW-04	49.9	3.5	-4.5	Fertilizer and/or Animal Waste
WW-05	12.8	9.7	7.1	Animal Waste

[a]The nitrate concentrations are from the UNL isotopic analysis.

[b]Interpretation of dominant sources is based on the following:

- $\delta^{15}N\text{-}NO_3$. Values less than 2.0 = dominated by synthetic fertilizer; values between 2.0 to 8.4 = undetermined mixture of synthetic fertilizer and/or animal waste; values greater than 8.4 = dominated by animal waste.
- $\delta^{18}O\text{-}NO_3$ values greater than 20.0‰ provide evidence for some atmospheric contribution. $\delta^{18}O\text{-}NO_3$ values below 20.0‰ could have an atmospheric contribution, but it becomes indistinguishable from other sources.

[c] Animal waste can be either human or non-human waste

NM – the sample was not measured because of the low nitrate concentrations.

The dominant source of nitrate for WW-05 is likely animal waste based on the interpretation of dominant sources indicated above for animal waste. The dominant sources for WW-02 are indeterminate given the low nitrate value. The dominant sources for WW-03 are likely synthetic fertilizer and/or animal waste with some atmospheric contribution, while the dominant sources for WW-04 are likely synthetic fertilizer and/or animal waste.

5. HAAK DAIRY: AGE DATING

Age dating analysis was conducted on the water well samples to estimate the length of time since the water infiltrated from the surface to the aquifer, including transport time to the wells. The reported ages may not correspond to when the water became contaminated. Two SF_6 samples were collected from each well and the values were averaged (Table 15). The age of the water in the Haak Dairy supply well and the downgradient wells ranged from approximately 16 to 25 years.

Table 15: Haak Dairy – Results of Age Dating Analyses Performed for Wells Reported in Years Since the Water Infiltrated From the Surface to the Aquifer.

Sample Location	Sample Age (years)	Duplicate Age (years)	Average (years)
WW-01: Upgradient Well	Over Value[a]	Over Value	NA
WW-02: Supply Well	15.8	16.3	16.1
WW-03: Downgradient Well	24.8 (J)	25.8 (J)	25.3
WW-04: Downgradient Well	21.8 (J)	23.3 (J)	22.6
WW-05: Downgradient Well	18.3 (J)	20.8 (J)	19.6

[a] Over value means that the sample contained more SF_6 than can be explained by equilibrium with modern air.

J – the analyte was positively identified, but the associated numerical value is an estimate.

6. HAAK DAIRY: SUMMARY OF RESULTS FOR RESIDENTIAL WATER WELLS

Table 16 summarizes the nitrate levels and compounds detected in the water wells upgradient and downgradient of the Haak Dairy and the compounds also detected in the source areas sampled on the dairy along with conclusions from the isotopic analysis. Total coliform, but not *E. coli* or fecal coliform, was detected in WW-04. The age of the water in the Haak Dairy supply well and the downgradient wells ranged from approximately 16 to 25 years.

All of the residential water wells except WW-01, the upgradient well, have nitrate levels that exceed the MCL of 10 mg/L. The concentration of total nitrogen, six major ions (chloride, calcium, magnesium, potassium, sodium, and sulfate), and two metals (barium and zinc) increased from the upgradient well to the downgradient wells at the Haak Dairy, with the highest concentrations detected in the dairy lagoon, dairy manure pile, and dairy application field samples. Alkalinity showed a similar pattern. Sample LG-01 was taken from liquid waste in a ditch just before entering the lagoon system and contained sulfate. Sulfate was not detected in co-located samples LG-02 and LG-03, likely because of anoxic conditions in the lagoon.

EPA evaluated four groups of organic compounds: pesticides; trace organics; pharmaceuticals; and hormones as part of this study. Atrazine was the only pesticide detected in the water well samples. Atrazine is widely used throughout the area, and the source is likely historical and current use of the pesticide, which may or may not be associated with dairy operations. EPA's Manchester Laboratory was unable to quantify the pesticide concentrations in the lagoon samples as a result of matrix interference. Atrazine was detected in the dairy field application sample. Several other pesticides were detected in the manure pile samples and application field samples but were not detected in the water wells.

The only trace organic detected in the water wells was bis-(2-ethylhexyl) phthalate (DEHP). DEHP was not detected in any of the dairy lagoons and was not analyzed for in the dairy manure pile or application field samples. Several trace organics were detected in all three dairy lagoons (for example, beta-sitosterol, beta-stigmastanol, and phenol) but not in the water wells.

Table 16: Haak Dairy – Comparisons of General Chemistry and Organic Compounds Detected in Wells and Dairy Operations and Assessment of Nitrate Sources in the Residential Wells Using Isotopic Analyses

Residential Well Number	Nitrate Concentration (mg/L)[a]	General Chemistry in Well	Organic Compounds Detected in Well	Organic Compounds also Detected in Dairy Sources	Dominant Source(s) of Nitrate Based on Isotopic Analyses
WW-01 Upgradient Well	0.38	No trends in total nitrogen or major ions as this is an upgradient well	Atrazine DEHP Testosterone Monensin	Not applicable. WW-01 is an upgradient well.	Not measured because lack of nitrate in sample
WW-03 Downgradient Well	34	Total nitrogen concentrations increased 90 –fold compared with the upgradient well. Three- to 65-fold increase in concentrations of six major ions compared with the upgradient well.	DEHP Tetracycline, Testosterone Monensin	Tetracycline (all dairy sources) Testosterone (LG-01) Monensin (all dairy sources)	Fertilizer and/or animal waste with some atmospheric contribution
WW-04 Downgradient Well	49.9	Total nitrogen concentrations increased over 100-fold compared with the upgradient well. Four- to 45-fold increase in concentrations of six major ions compared with the upgradient well.	Atrazine Tetracycline Chlortetracycline Testosterone Monensin	Atrazine (S0-02) Tetracycline (all dairy sources) Chlortetracycline (LG-02 and SO-02) Testosterone (LG-01) Monensin (all dairy sources)	Fertilizer and/or animal waste
WW-05 Downgradient Well	12.8	Total nitrogen concentrations increased more than 30-fold compared with the upgradient well. Four- to over 10-fold increase in concentrations of six major ions compared with the upgradient well.	Atrazine Testosterone Monensin	Atrazine (SO-02) Testosterone (LG-01) Monensin (all dairy sources)	Animal waste

[a] Nitrate results are from Cascade Analytical Laboratory

There were no wastewater pharmaceuticals detected in the water wells associated with the Haak Dairy. Thiabendzadole and DEET were each detected in one dairy lagoon while no compounds were detected in the manure pile or application field samples. For the veterinary pharmaceuticals, three compounds were detected in the water wells (chlortetracycline, tetracycline and monensin). Chlortetracycline was detected in one downgradient well and in one dairy lagoon and the application field sample. Tetracycline was detected in two of the three downgradient wells and in all three dairy lagoons, the dairy manure pile, and the dairy application field samples. Monensin was detected in the upgradient well and in the three downgradient wells. Monensin was detected in all the dairy lagoons and the dairy manure pile and dairy application field samples. Several additional compounds were detected in the dairy lagoons, dairy manure pile, and application field samples.

Two hormones were detected in water wells (testosterone and epitestosterone). Testosterone was detected in all five water wells with the highest concentration in the upgradient well, and in one lagoon but not in the manure pile or application field samples. Epitestosterone was detected in one downgradient well but not in any other source.

The isotopic data indicates that the source of nitrate in each of the wells varies. For WW-02, the source is indeterminate given the low nitrate value. The possible likely sources in WW-03 are fertilizer and/or animal waste with an atmospheric contribution. The dominant sources in WW-04 are likely fertilizer and/or animal waste. The likely dominant source in water well WW-05 is animal waste.

In conclusion, all of the residential water wells except WW-01 (the upgradient well as determined by general USGS flow direction) have nitrate levels above the MCL. The total nitrogen and major ions data indicate that the Haak Dairy is likely releasing nitrogen and six major ions to the groundwater and is a likely source of those higher levels in downgradient wells. The metals barium and zinc and alkalinity show a similar pattern. Information on the construction and depth of the upgradient well would be helpful to verify groundwater flow direction and clarify the contributions of sources to the higher concentrations seen from the upgradient well to the downgradient wells.

The Haak Dairy is a likely source of the tetracycline detected in the two downgradient residential water wells. The multiple detections of monensin in the Haak Dairy sources and in the downgradient wells indicates monensin is being used at the Haak Dairy and is a possible source in the downgradient wells. The isotopic data provide good evidence that animal waste (human or non-human) is a dominant contributor to the nitrate contamination for WW-05.

B. Dairy Cluster

The “Dairy Cluster” refers to a group of dairies north of the Yakima River. The Dairy Cluster is located about 2 miles north of the town of Liberty, near the northern edge of the irrigated area in the Yakima Valley. George DeRuyter & Son Dairy and the D and A Dairy are treated as two separate facilities, although they have some common ownership (“DeRuyter Dairy” and “D and A Dairy”- see Figure 14). Cow Palace 1 and 2 comprise a single facility (“Cow Palace” - see Figure

14). Liberty Dairy and Bosma Dairy are adjacent to one another and share some facilities and so are treated as a single facility ("Liberty and Bosma Dairies" - see Figure 14). The facilities generally consist of cow pens, milking parlors, animal waste lagoons, and animal waste application fields. Irrigation ditches run through the dairy properties.

EPA selected these dairies for this study because they met the criteria identified in the study plan (see Section VI.C.1). Specifically, the Dairy Cluster has: high concentration of animals per acre[25]; dairy inspection reports (WSDA 2012) indicate that elevated levels of nitrogen had been measured in dairy application fields in the past; the dairies are located near the northern edge of cultivated land in the Valley with relatively few upgradient potential sources of nitrogen; and drinking water wells downgradient of the dairies showed levels of nitrate significantly elevated above the MCL.

Numbers of Animals and Amount of Waste Generated

The WSDA provides the ranges for the number of animals at the Dairy Cluster facilities and the amount of waste generated including the estimated losses during storage of the waste (WSDA 2010) (See Table 17).

As a group, in 2009 the dairy cluster had more than 17,240 mature dairy cattle, and more than 7,000 heifers/calves. As discussed above, a farm with 2500 dairy cattle is similar in waste load to a city of 411,000 people (EPA 2004). A difference lies in the fact that human waste is treated before discharge into the environment, but animal waste is either not treated at all or minimally treated before discharge into the environment (EPA 2004). Applying this estimate to the Dairy Cluster range of 17,240 to 19,378 mature dairy cattle, the Dairy Cluster produces an amount of waste similar to a community of more than 2,827,000 people.[26] This estimate is based only upon the numbers of mature dairy cattle. It does not include the additional waste load of heifers and calves. For comparison, the human population of Yakima County in 2010 was 243,231.[27]

Sizable amounts of nitrogen, a component of manure, are generated by the dairies. Nitrogen production can be roughly estimated for each dairy by applying the ranges of the numbers of animals to formulas used by the WSDA to estimate manure and nitrogen production (WSDA 2010). As a whole, the Dairy Cluster generates more than 500,000 tons of manure each year equating to more than 3,100 tons of nitrogen.

[25] Cow Palace had 23 cows per acre. The number of cows per acre at specific Yakima County dairies ranged from 1 to 34. Cow Palace had the second-highest ratio in the county (WSDA 2010). Cows per acre ratios are not static and have changed since EPA began this study.

[26] Calculations: "Mature dairy cattle estimate": 5,700 cows + 6,840 cows +4,700 cows = 17,240 cows (low end of range for each dairy). 411,000 persons divided by 2500 dairy cows equals 164 persons per cow. 17,240 cows times 164 persons per cow equals 2,827,360 persons. Rounded off to the nearest thousand equals 2,827,000 persons.

[27] U.S. Census Bureau: http://quickfacts.census.gov/qfd/states/53/53077.html

Table 17: Dairy Cluster – Approximate Numbers of Dairy Cattle, Annual Manure Production, and Annual Nitrogen Production

Mature Dairy Cattle	Heifers and Calves	Annual Manure Production (tons) [a]	Annual Nitrogen Production as Excreted [b] (tons)	Annual Nitrogen After 35% Losses Occur [c] (tons)
Liberty and Bosma Dairies				
5,700 to 6,839	1,000 to 1,999	155,040 to 193,950	984 to 1,220	640 to 793
Cow Palace				
More than 6,840	2,000 to 2,999	More than 188,570	More than 1,200	More than 780
DeRuyter and D and A Dairies				
4,700 to 5,699	More than 4,000	More than 161,460	More than 977	More than 635

[a]Annual manure production is calculated using the following formula: [((# of milking cows)*1.4*108) + ((# of dry cows)*1.4*51) + ((# of heifers)*0.97*56) + ((# of calves *0.33*83)]*365/2000 (WSDA 2010)

[b]Nitrogen production is calculated using the following formula: [((# of milking cows)*1.4*.71) + ((# of dry cows)*1.4*.3) + ((# of heifers)*0.97*.27) + ((# of calves *0.33*.42)]*365/2000 (WSDA 2010)

[c]Losses caused by volatilization or denitrification during storage are estimated at 35%. This estimate does not include application losses.

The WSDA estimates that during storage at a typical dairy, about 35 percent of the nitrogen in dairy waste is "lost" through the process of volatilization or denitrification (WSDA 2010). The formula does not assume any leakage into the subsoils from the lagoons or other structures or conveyances. If the remaining nitrogen is not taken up by crops grown on application fields or transported offsite to another location, it may end up in the groundwater. For the Dairy Cluster as a whole, more than 2,050 tons of nitrogen remain after losses.

WASTE MANAGEMENT

The dairies in the Dairy Cluster use a variety of animal waste storage methods, including lagoon systems, dry stacking, manure pits, composting, above ground tanks, and (at the DeRuyter Dairy) an anaerobic digester.

All the facilities in the Dairy Cluster use their own lagoon systems to store animal wastes. The nitrogen-rich liquids that leak through the bottom and sides of the lagoons can migrate downward through the soil column to the drinking water aquifer. EPA estimated the surface areas of the Dairy Cluster lagoon systems using aerial photographs. The lagoon systems' storage capacities were derived from WSDA inspection reports (Table 18).

Table 18: Dairy Cluster – Lagoon System Surface Area, Storage Capacity, and Approximate Leakage Rate

Dairy	Approximate Lagoon System Liquid Surface Area (square feet)	Lagoon System Storage Capacity (gallons)[28]	Estimated Lagoon System Leakage, Based on Unit Seepage Rate of 500 Gallons per Acre per Day (gallons per year)	Estimated Range of Lagoon System Leakage, Based on Ham Seepage Rate Range (gallons per year)
Liberty and Bosma Dairies	932,600	67,000,000	3,744,000	1,700,000 to 20,000,000
Cow Palace	400,000	40,800,000	1,606,000	720,000 to 8,600,000
DeRuyter and D and A Dairies	508,400	33,000,000	2,041,000	910,000 to 11,000,000

In combination, the Dairy Cluster lagoon systems have a surface area of approximately 1,841,000 square feet (equivalent to about 32 football fields – assumes a football field is 57,600 square feet). The lagoons have a combined maximum storage capacity of about 126,800,000 gallons, the equivalent volume of about 192 Olympic-size swimming pools (assumes the capacity of an Olympic-size swimming pool is 660,000 gallons).

As discussed previously, the NRCS Washington recommends avoiding the use of "agricultural waste storage ponds" (lagoons), unless no reasonable alternative exists, at locations like the Dairy Cluster where there is an aquifer that serves as a domestic water supply (NRCS Washington 2004). Assuming the same unit seepage rate as for the Haak Dairy (500 gallons per acre per day), seepage volume at the Dairy Cluster is approximately 7,391,000 gallons per year. This is the equivalent volume of about 11 Olympic-size swimming pools annually.

Based on the Ham and DeSutter study (Ham 2002), a lined lagoon system with a similar surface area would release approximately 3,330,000 to 39,600,000 gallons per year into the underlying soils, the equivalent of about five to 60 volumes of Olympic-size swimming pools annually.

Leakage rates for the Dairy Cluster lagoons would likely be greater than the above estimates if the lagoons are unlined, especially if they are constructed in well drained, highly permeable soils. If the lagoons are lined with a plastic liner, the actual leakage rates could be lower, although plastic liners are easily punctured during construction and lagoon maintenance and, therefore, also leak. The most effective liner system incorporates both plastic and clay layers.

[28] Lagoon systems are generally designed to hold about one third of a dairy's annual liquid waste generation (the amount that would be generated over a four month time period).

EPA requested information from the Dairy Cluster dairies about how their lagoons are constructed, but they declined to provide the information. EPA has asked Yakima County, the WSDA, the Washington Department of Ecology, and the NRCS if any of the Dairy Cluster lagoons have engineered liners, but none of the agencies could affirm that they do. EPA is unaware of any state or local requirements that would compel dairies in Yakima County to construct lagoons to any specific level of permeability.

Utilization rates of the lagoon systems vary and are indicated in the WSDA inspection reports (WSDA 2012). Table 19 provides a summary of the lagoon system information contained in the inspection reports. A dashed line indicates no information was provided in the reports for a particular data element.

Table 19: Dairy Cluster – Washington State Department of Agriculture Inspection Dates and Reported Values for Lagoon Capacity

Date of Inspection	Lagoon Capacity (gallons)	Number of Days of Lagoon Capacity[a]	Percent of Lagoon Capacity Utilized at Time of Inspection	Number of Lagoons
Liberty and Bosma Dairies				
3/2/1011	67,000,000	-----	-----	17
1/26/2010	67,000,000	120 days plus	60%	13
4/24/2008	67,000,000	120 days plus	60%	-----
7/18/2006	67,000,000	1 year plus	60%	-----

D and A Dairy				
1/25/2011	8,000,000	-----	-----	5
12/4/2008	9,000,000	4 months plus	35%	-----
1/11/2007	-----	-----	60%	-----

[a]"Number of Days of Lagoon Capacity" is an estimate of the maximum number of days a lagoon system could accept liquid dairy waste under normal operating conditions without having to be pumped out. It is intended to assess whether a lagoon system is sufficiently large enough to hold liquid waste generated by the dairy throughout the winter months, without having to be pumped out to the waste application fields when there are no crops growing that could take up the nutrients in the waste. It assumes the lagoon system was completely pumped out at the beginning of the time period.

SURFACE SOILS

Surface soils in Yakima County have been characterized and mapped by the U.S. NRCS (NRCS 2012). A soil report has been developed for each of the dairies (EPA 2012a) and is summarized in Appendix B. Almost all the surface soils underlying the Dairy Cluster have a "well drained" classification, which means water moves readily through the soil.

More than 80 percent of the surface soils underlying the Dairy Cluster have a high saturated hydraulic conductivity. The percentage of surface soils with a "high" saturated hydraulic conductivity at the dairies is approximately: 88 percent at the Liberty and Bosma Dairies; 82 percent at the Cow Palace; and 93 percent at the DeRuyter and D and A Dairies. The permeability of the surface soils at the different dairies is more fully described in Appendix B.

Animal waste applied to crop fields can be a significant source of nitrogen loading to the soil, groundwater, and surface water. Applying large quantities of animal wastes on highly permeable surface soils (i.e., soil with a high hydraulic conductivity) increases the risk of groundwater contamination because water from irrigation or precipitation can readily infiltrate the soil surface and carry nitrogen past the root zone before it can be taken up by plants (EPA 2004). Agronomic nitrogen application rates are typically based on soil types and crop yield goals. However, agronomic nitrogen application rates are not necessarily protective of drinking water.

APPLICATION FIELDS

All the dairies in the Dairy Cluster apply animal wastes as fertilizer onto application fields that they own or lease according to WSDA inspection reports (WSDA 2012). Corn and triticale (a cross of wheat and rye) are typical crops grown by dairies because they have high nitrogen needs and can be used as feed. Animal waste application fields can be a significant source of nitrogen loading to the soil and potentially the groundwater and surface water.

n general, Washington law restricts WSDA ability to disclose to the public the exact size of application fields, but WSDA can release the information in ranges (WSDA 1996). The Liberty Dairy and Bosma Dairy own or lease between 1,800 and 2,500 acres of application fields; the Cow Palace owns or leases between 551 and 900 acres; and the DeRuyter Dairy and D and A Farms Dairy own or lease between 3,201 and 4,000 acres (WSDA 2010).

The dairies employ a variety of animal waste application methods, including spreaders ("honey wagons"), "big gun" sprinklers, sprinkler irrigation systems, dry spreaders, and custom applicators. If a dairy does not have enough land on which to apply the waste within agronomic rates, excess waste may be transferred offsite to another user.

WSDA inspectors noted in their reports for the Dairy Cluster that elevated levels of nitrogen were detected in some of its application fields in the past (WSDA 2012). Excessive amounts of nitrogen on highly permeable, irrigated surface soils pose a threat to groundwater. In addition, WSDA records indicate the dairies in the Dairy Cluster exported some of their animal wastes to other landowners.

For this study, the samples were collected from the following dairies: DeRuyter Dairy; D and A Dairy; Cow Palace; and Liberty and Bosma Dairies. Figures 11 and Figures 15 show the sample locations for the Dairy Cluster. The sampling locations include:

- One upgradient drinking water well (WW-06) located north (upgradient) of the other sample locations in the Dairy Cluster.
- Dairy supply wells located on the DeRuyter Dairy (WW-07); D and A Dairy (WW-08); and Cow Palace (WW-09). The supply well at the Liberty and Bosma Dairies was not sampled because it has a water treatment system.
- One dairy manure pile sample was collected from each of the following dairies: DeRuyter Dairy (SO-03), D and A Dairy (SO-05); Cow Palace (SO-07); and Liberty and Bosma Dairies (SO-09).
- Twelve dairy lagoon samples:
  - DeRuyter Dairy (LG-04, LG-05, and LG-06. These samples were collected from three separate lagoons);
  - D and A Dairy (LG-07, LG-08, and LG-09. LG-08 and LG-09 were collocated);
  - Cow Palace (LG-10, LG-11, and LG-12. LG-11 and LG-12 were collocated); and
  - Liberty Dairy (LG-13 and LG-14) and Bosma Dairy (LG-15). These samples were collected from three separate lagoons.
- Four dairy application field samples;
  - DeRuyter Dairy (SO-04);
  - D and A Dairy (SO-06);
  - Cow Palace (SO-08); and
  - Liberty and Bosma Dairies (SO-10).
- Eight downgradient residential drinking water wells (WW-10 to WW-17).

1. DAIRY CLUSTER: GENERAL CHEMISTRY

The four types of general chemistry data collected at the Dairy Cluster were: nitrate and other forms of nitrogen; major ions; minor ions and trace inorganic elements; and perchlorate. Each of these is discussed below.

Dairy Cluster: Nitrate and Other Forms of Nitrogen

Twelve water well and 12 dairy lagoon samples were analyzed for nitrate, nitrate plus nitrite, ammonia or ammonium, and TKN. The dairy manure pile and dairy application field samples were analyzed for extractable nitrate-N (Nitrate-N Solid), extractable ammonia-N (Ammonia-N Solid), and total nitrogen by combustion (Total Nitrogen Solid). Table 20 summarizes the nitrate and other forms of nitrogen data. In addition, total nitrogen from all forms was calculated for each sample and is presented as "Calculated Total Nitrogen" in Table 20.

Table 20: Dairy Cluster – Distribution of Total Nitrogen in Wells, Dairy Lagoons, Manure Piles, and Application Fields

Location	Nitrate as N (ppm)	Nitrate + Nitrite as N (ppm)	Ammonia as N (ppm)	TKN as N (ppm)	Calculated Total Nitrogen (ppm)
Water Wells and Lagoons					
WW-06: Upgradient Well	0.71	0.73	ND	ND	0.73
WW-07: Supply Well	1.02	1.19	ND	ND	1.19
WW-08: Supply Well	11.7	12.9	ND	ND	12.9

Location	**Ammonium as N (ppm)**	**Nitrate + Nitrite as N (ppm)**	**Total Nitrogen Solid (ppm)**	**Total Nitrogen (ppm)**
SO-04: Application field	7.3	247	2110	2110
SO-06: Application field	6.8	45.6	960	960
SO-08: Application field	2.9	84.3	3040	3040
SO-10: Application field	7.1	139	3590	3590

J – the analyte was positively identified, but the associated numerical value is an estimate.

Figure 15 shows the concentration of total nitrogen for the samples collected at the Dairy Cluster. As with the Haak Dairy, the total nitrogen concentrations are higher in the downgradient wells compared with the upgradient well, with several significant sources of nitrogen in between (such as dairy lagoons, dairy manure piles, and dairy application fields). The concentration of nitrate in the upgradient well is within background range. Nitrate concentrations in some downgradient wells are more than four times the MCL. The data suggest that the Dairy Cluster is a likely source of the increased nitrogen levels in the downgradient wells.

Dairy Cluster: Major Ions

Figures 16a, 16b, and 16c shows the concentrations of several major ions in the upgradient water wells, the supply wells, the lagoons, and the downgradient wells. An average concentration for the three lagoon samples collected in each of the four areas was calculated (LG-04, LG-05, and LG-06; LG-07, LG-08, and LG-09; LG-10, LG-11, and LG-12; and LG-13, LG-14, and LG-15). The average concentrations were calculated for the four sets of lagoon samples to allow for easier comparison of the data.

The figures show a similar pattern to that observed at the Haak Dairy, with elevated concentrations in the downgradient wells (WW-10 to WW-17) compared with the upgradient wells (WW-06) and the supply wells (WW-07 to WW-09), with the highest concentrations in the lagoons. Alkalinity also showed a similar pattern. The increase in the concentrations ranges from up to: seven-fold for sodium; nine-fold for magnesium; 10-fold for calcium; and more than 30-fold for chloride. Potassium showed a slight increase. As with the Haak Dairy, sulfate showed the largest increase in concentration between the upgradient and downgradient wells. As with the Haak Dairy, the dairy sources are a likely source of major ions in the downgradient water wells.

Dairy Cluster: Minor Ions and Trace Inorganic Elements

All water well and dairy lagoon samples were analyzed for minor ions and trace elements, but the dairy manure pile and dairy application field samples were not analyzed (Table C6 in Appendix C). The trace inorganic elements found in both the water wells and the dairy lagoons included barium, iron, manganese, mercury, and zinc. Barium was detected in all 11 wells, iron was detected in five wells, manganese was detected in four wells, mercury was detected in one well, and zinc was detected in eight wells. Barium was the only trace inorganic element that increased between the upgradient well and the downgradient wells, with the highest concentrations in the lagoons.

Dairy Cluster: Perchlorate

Perchlorate analysis was performed on all of the water samples collected from wells near the dairies (Table C7 in Appendix C). The concentrations ranged from less than the detection limit (0.003 µg/L) to 3.08 µg/L (WW-17). Perchlorate analysis was conducted to augment the isotopic data as an indicator of potential accumulation of atmospherically derived nitrate associated with caliche soils. The dairy lagoon samples were not analyzed for perchlorate because this compound is rapidly degraded in anoxic environments, such as a dairy lagoon.

2. DAIRY CLUSTER: MICROBIOLOGY

There were no detections of total coliform, fecal coliform, or *E. coli* in the water well or supply well samples associated with the Dairy Cluster with the exception of water well WW-06 which had a detectable level of total coliform. *E. coli* was not detected in WW-06 and therefore MST was not completed for this well or for any of the wells because there was no indication of fecal contamination.

All the dairy lagoons in the Dairy Cluster were analyzed for fecal coliform. Samples LG-04 through LG-09 also were analyzed for *E. coli* and MST was performed. *E. coli* or MST analyses were not performed on the other lagoon samples (LG-10 to LG-15) because EPA's mobile microbiology laboratory was available to participate in the sampling effort for only a limited period of time (Table C8 in Appendix C).

All the dairy lagoons had high levels of fecal coliform. Of the six dairy lagoons evaluated using MST, five indicated a ruminant source (LG-04, LG-05, LG-06, LG-07, and LG-08) while one indicated both a ruminant and a human source (LG-09). It is unknown why human waste was detected in LG-09 at the D and A Dairy, given that this facility likely is on a septic system.

3. DAIRY CLUSTER: ORGANIC COMPOUNDS

Dairy Cluster: Pesticides

Four pesticides (atrazine, bentazon, alachlor, and ioxynil) were detected in the water wells associated with the Dairy Cluster. Atrazine, bentazon, and alachlor are pesticides commonly used in agricultural crop production. Ioxynil is not registered for use in the United States (PAN 2011).

- Atrazine: WW-06 (upgradient well) and downgradient wells WW-12, WW-13, WW-14, WW-15, WW-16, and WW-17
- Bentazon:WW-08 (dairy supply well)
- Alachlor:WW-13 and WW-17
- Ioxynil: WW-13

No results are reported for pesticides in the dairy lagoon samples because the laboratory experienced problems with interferences as a result of the complex nature of the sample media. The four pesticides detected in the water wells were not detected in the dairy manure pile or dairy application field samples.

The concentrations of atrazine found in the water wells ranged from 0.016 µg/L to 0.19 µg/L. None of the samples exceed the MCL for atrazine of 3 µg/L. Alachlor levels found in two water wells were 0.048 µg/L and 0.057 µg/L. None of the samples exceed the MCL for alachlor of 2 µg/L. The concentration of bentazon in water well WW-08 was 0.036 µg/L. The concentration of ioxynil in well sample WW-13 was 0.063µg/L. There are no MCLs established for bentazon or ioxynil.

The four pesticides are not anticipated to be used in animal operations at the dairies for pest control (Pike 2004), but atrazine, alachlor, and bentazon are commonly used in corn production.

Each of the dairies includes crop land where pesticides may have been applied. Given the historical use of these pesticides and the detection of these compounds in other studies, it is likely that these pesticides are from the current and historical use of pesticides for agriculture, which could include application by the dairies on the associated fields. See Table C9 in Appendix C for all the results.

Seven pesticides were detected in one or more of the dairy manure pile samples. These pesticides were not detected in the water well samples. Seven pesticides were also detected in one or more of the field application samples, but they were not detected in the water well samples.

Dairy Cluster: Trace Organics

Three compounds were detected in water well samples associated with the Dairy Cluster:

- Bis-(2-ethylhexyl) phthalate (DEHP) in WW-06 (upgradient well), WW-11, and WW-17
- Naphthalene in WW-07 (supply well)
- Tetrachloroethylene in WW-07 (supply well).

Of the three compounds found in water wells, only DEHP was found in one dairy lagoon sample (LG-10). DEHP is a common plasticizer and could come from a variety of sources. Naphthalene and tetrachloroethylene were not detected in any of the dairy lagoons.

All 12 dairy lagoons associated with the Dairy Cluster had one or more detection of trace organics (Table C10 in Appendix C). Eight compounds were detected in all 12 dairy lagoons associated with the Dairy Cluster. These compounds are generally the same as those detected at the Haak Dairy: 3-beta-coprostanol; 3-methyl-1h-indole (skatol); 4-nonyphenol monoethoxylate; beta-sitosterol; beta-stigmastanol; cholesterol; p-cresol; and phenol. Trace organics were not analyzed in manure or soil samples.

Dairy Cluster: Pharmaceuticals

Only one wastewater pharmaceutical, DEET, was detected in a single downgradient well (WW-10). There were no detections of any of the wastewater pharmaceuticals in the dairy manure pile or dairy field application samples. Three wastewater pharmaceutical compounds were detected in dairy lagoons associated with the Dairy Cluster: DEET (eight dairy lagoons); diphenhydramine (two dairy lagoons); and thiabendazole (three dairy lagoons). The source of the DEET could be its use as an insect repellent. The source of the diphenhydramine in the dairy lagoons is unknown. Diphenhydramine is a common antihistamine used by people and can be used on dogs and cats. Thiabendzadole is a parasiticide that is used to treat worm infections in both livestock and humans and can be used as a pesticide (Mayo Clinic 2011).

Table 21 indicates the veterinary pharmaceuticals that were detected in one or more water well samples and in the dairy lagoons, dairy manure piles, and dairy application field samples. Five veterinary pharmaceuticals were detected in the water wells (chlortetracycline, monensin, tetracycline, tylosin, and virginiamycin). Veterinary pharmaceuticals were not detected in water wells WW-12 and WW-16 and lagoon sample LG-04.

Table 21: Dairy Cluster – Concentrations of Five Veterinary Pharmaceuticals in Wells, Lagoons, Manure Piles, and Application Fields

Sample Location[a]	Chlortetracycline	Monensin	Tetracycline	Tylosin	Virginiamycin

WW-14	ND	0.033	ND	ND	0.024
WW-15	0.119	ND	ND	ND	ND
WW-17	ND	ND	0.049	ND	ND

[a]Water wells WW-12 and WW-16 had no detections and dairy lagoon sample LG-04 had no detections of these five compounds.

J – the compound was positively identified, but the associated numerical value is an estimate.

ND – not detected.

R – the data are unusable for all purposes because of analytical problems with the sample.

Monensin was not detected in the upgradient well. Monensin was detected in WW-10 and WW-14, and was also detected in all the dairy lagoons (exception of LG-07), dairy manure piles, and dairy application field samples. These detections indicate that monensin is likely used at the dairies in the Dairy Cluster. The dairies are a likely source of the monensin in WW-10 and WW-14. This conclusion is reinforced by the isotopic findings, which indicate that the source of nitrate for WW-14 is animal waste (although animal waste can be either human or non-human).

Tetracycline was detected in the upgradient well (WW-06) and in two downgradient wells, which had lower concentrations than the upgradient well (WW-11 and WW-17). Tetracycline was detected in all of the dairy lagoon samples, dairy manure pile samples, and dairy application field samples, indicating that tetracycline is used at the dairies. It is possible that the dairy sources are one of the sources of the tetracycline in the downgradient wells. However, given that the concentrations in the upgradient well are higher than the downgradient wells, another source for the tetracycline is likely.

Tylosin was detected in one downgradient well (WW-11) and five of the dairy lagoons, along with several dairy manure pile and dairy application field samples. Virginiamycin was detected in two downgradient wells (WW-13 and WW-14) and six dairy lagoons but not in any of the dairy manure piles or application field samples. Chlortetracycline was detected in dairy lagoons and manure and soil samples and in one downgradient well (WW-15). The data suggest the dairies are possible sources of these substances in the downgradient wells.

Several other veterinary pharmaceutical compounds (ractopamine, sulfachloropyridazine, sulfadimethoxine, sulfamethazine, and sulfathiazole) were detected in the majority of dairy lagoon, dairy manure pile, and dairy application field samples but were not detected in downgradient water wells. This finding would indicate they are being used by the dairies in the Dairy Cluster.

Dairy Cluster: Hormones

EPA's Ada Laboratory analyzed the liquids samples (water wells and dairy lagoons), but not the solids samples (dairy manure pile and dairy application fields) for five hormones. The laboratory did not detect any of the five hormones in water wells associated with the Dairy Cluster; however three of these five hormones (17-α-estradiol, 17-β-estradiol, and estrone) were detected in all 12 of the dairy lagoons. The hormones 17-α-ethyl-estradiol and estriol were not detected in any of the Dairy Cluster lagoon samples (Table C13 in Appendix C).

The UNL Laboratory analyzed the Dairy Cluster liquids and solids samples for 20 hormones, including the five hormones that the EPA's laboratory analyzed. The UNL Laboratory detected 17-α-estradiol in the upgradient well (WW-06) and in one supply well (WW-08) but not in any of the downgradient wells. The UNL Laboratory also detected 17-β-estradiol and estrone in one supply well (WW-09).

For all the 20 hormones analyzed by UNL, four were detected in an upgradient well or in a downgradient well (17-α-estradiol, androstadienedione, androsterone, and testosterone) (Table 22).

Table 22: Dairy Cluster – Concentrations of Four Hormones in Wells, Lagoons, Manure Piles, and Application Fields

Sample Location[a]	17-α-Estradiol[b]	Androstadienedione[b]	Androsterone[b]	Testosterone[b]
Upgradient Water Well (reported as µg/L)				
WW-06	0.003	ND	ND	0.005
Dairy Supply Wells (reported as µg/L)				
WW-08	0.003	0.002 (J)	ND	0.003
WW-09	ND	ND	0.005 (J)	0.008
Dairy Lagoons (reported as µg/L)				
LG-05	ND	3.50	ND	0.193
LG-06	ND	ND	ND	0.195
LG-07	ND	ND	ND	0.016
LG-08	0.383	ND	ND	0.090
LG-09	0.844	ND	ND	0.007
LG-10	0.459	ND	ND	0.028
LG-11	2.92	0.166	ND	ND
LG-12	3.27	0.20	ND	0.024
LG-13	ND	ND	ND	0.262
LG-14	ND	ND	ND	0.170
LG-15	ND	ND	ND	ND
Dairy Manure Piles and Dairy Application Fields (reported as µg/kg)				
SO-03	34.7	29.4	ND	2.95
SO-05	ND	15.4	ND	ND
SO-06	0.11	ND	ND	ND
SO-07	18.7	13.5	ND	ND
SO-09	16.9	19.3	ND	ND
Downgradient Water Wells (reported as µg/L)				
WW-11	ND	ND	ND	0.004
WW-12	ND	0.004 (J)	0.018 (J)	ND
WW-15	ND	ND	0.019 (J)	ND
WW-17	ND	ND	0.008 (J)	ND

[a]The four hormones were not detected in dairy supply well (WW-07), four downgradient water wells (WW-10, WW-13, WW-14, and WW-16), one dairy lagoon (LG-04) and three dairy application field samples (SO-04, SO-08, and SO-10).

[b] Analyses were conducted by the UNL Laboratory

J – the compound was positively identified, but the associated numerical value is an estimate.

ND – not detected.

The hormone 17-α-Estradiol was detected in the upgradient well and in several of the dairy lagoons and dairy manure pile samples but not in any of the downgradient wells. Androstadienedione was detected in one downgradient water well and several dairy lagoons and

dairy manure pile samples. Androsterone was detected in three downgradient wells but not in any of the dairy sources. Testosterone was detected in the upgradient well and two downgradient wells and in the majority of the dairy lagoons. The concentration in the upgradient well was greater than the downgradient wells. It is possible that the dairies are a source of androstadienedione and testosterone in the downgradient wells; however, given the detection of testosterone in an upgradient well, other sources are likely.

4. DAIRY CLUSTER: ISOTOPIC ANALYSIS

Isotopic analyses were completed for water wells WW-06 to WW-17 (Table 23) by the UNL Laboratory. There was insufficient nitrate in WW-06, WW-09, and WW-10 to complete the analysis. Additional details on the results of isotopic analyses conducted for this study are provided in Appendix D of this report.

Table 23: Dairy Cluster – Concentration of Nitrate in Water Wells, Isotopic Signatures, and the Interpreted Dominant Source of the Nitrate Based on the Observed Values

Location	Nitrate-N (mg/L)[a]	δ^{15}N-NO_3 (‰)	δ^{18}O-NO_3 (‰)	Interpreted Dominant Source(s)[b]
WW-06	0.6	NM	NM	NM
WW-07	1.1	-0.1	NM	Fertilizer
WW-08	11.7	5.3	23	Fertilizer and/or Animal Waste[c] with Some Atmospheric Contribution
WW-09	NM	NM	NM	NM
WW-10	NM	NM	NM	NM
WW-11	21.6	3.0	18	Fertilizer and/or Animal Waste
WW-12	43.6	6.2	-1.4	Fertilizer and/or Animal Waste
WW-13	42	11	16	Animal Waste
WW-14	40.7	10	8.5	Animal Waste
WW-15	27.4	5.2	30	Fertilizer and/or Animal Waste with Some Atmospheric Contribution
WW-16	23	5.9	5.8	Fertilizer and/or Animal Waste
WW-17	23.3	6.9	2.5	Fertilizer and/or Animal Waste

[a] The nitrate concentrations are from the UNL isotopic analysis.

[b] Interpretation of dominant sources is based on the following:

- δ^{15}N-NO_3. Values less than 2.0 = dominated by synthetic fertilizer; values between 2.0 to 8.4 = undetermined mixture of synthetic fertilizer or animal waste; values greater than 8.4 = dominated by animal waste.
- δ^{18}O-NO_3 values greater than 20.0‰ provide evidence for some atmospheric contribution. δ^{18}O-NO_3 values below 20.0‰ could have an atmospheric contribution, but it becomes indistinguishable from other sources.

[c] Animal waste can include both human and non-human waste

NM – the sample was not measured because of the low nitrate concentrations.

The dominant source of nitrate for WW-13 and WW-14 is likely animal waste while the dominant source of nitrate for WW-07 is likely fertilizer. The dominant sources of nitrate for WW-11, WW-12, WW-16, and WW-17 is likely a combination of synthetic fertilizer and/or

animal waste while the dominant sources for WW-08 and WW-15 is likely a combination of synthetic fertilizer and/or animal waste with some atmospheric contributions.

5. DAIRY CLUSTER: AGE DATING

Table 24 presents the age dating data and, similar to the Haak Dairy, two samples were collected for each water well.

Table 24: Dairy Cluster – Results of Age Dating Analyses Performed for Wells Reported in Years Since the Water Infiltrated From the Surface to the Aquifer

Location	Sample Age	Duplicate Age	Average of Samples	Average of Group
WW-06 – Upgradient	16.3 (J)	15.8 (J)	16.1	16.1
WW-07 – Supply Well	36.3 (J)	32.8 (J)	34.6	42.5
WW-08 – Supply Well	35.3 (J)	40.8 (J)	38.1	
WW-09 – Supply Well	58.3 (J)	51.3 (J)	54.8	
WW-10 – Downgradient Well	44.3 (J)	44.8 (J)	44.6	31.6
WW-11 – Downgradient Well	Over Value[a]	Over Value[a]	NA	
WW-12 – Downgradient Well	Over Value[a]	Over Value[a]	NA	
WW-13 – Downgradient Well	24.3 (J)	23.8 (J)	24.1	
WW-14- Downgradient Well	30.8	29.3	30.1	
WW-15 – Downgradient Well	27.8 (J)	28.3 (J)	28.1	
WW-16 – Downgradient Well	29.8 (J)	28.8 (J)	29.3	
WW-17 – Downgradient Well	33.3 (J)	33.8 (J)	33.6	

[a] "Over value" means that the sample contained more SF_6 than can be explained by equilibrium with modern air.

J – the compound was positively identified, but the associated numerical value is an estimate.

Averages were calculated for the upgradient well (WW-06), three supply wells (WW-07, WW-08, and WW-09), and the six downgradient wells with reported values (WW-10, WW-13, WW-14, WW-15, WW-16, and WW-17). The results indicate the youngest water was sampled in the upgradient well, with an average age of 16.1 years, which suggests that it is a relatively shallow well and is consistent with its upgradient location. The reported ages may not correspond to when the water became contaminated. The oldest waters were in supply wells associated with the Dairy Cluster, with an average age greater than 40 years. The average age of the waters in the downgradient wells was 31.6 years. These relative ages are generally consistent with available well log information indicating that the dairy supply wells are typically screened in the basaltic aquifer, and the downgradient residential wells are commonly screened in the shallower alluvial aquifer.

6. DAIRY CLUSTER: SUMMARY OF RESULTS FOR RESIDENTIAL WATER WELLS

Table 25 provides a summary of the groups of compounds (general chemistry and organic compounds) and analytical techniques (isotopic analyses) that provide information useful to address the question of the likely sources of the nitrate for the nine residential water wells associated with the Dairy Cluster. No microbial contamination was found in the downgradient wells. There appears to be a correlation between the age dating data and the well depths for those water wells that have well depth information (see Appendix A3).

As with the Haak Dairy, the nitrate levels in residential wells downgradient of the Dairy Cluster are greater than EPA's MCL for nitrate with the exception WW-10. Nitrate levels in the Dairy Cluster supply wells were generally low, with the exception of WW-08. This well serves the DeRuyter Dairy and D and A Dairy and was measured at 11.7 mg/L, which exceeds the MCL for nitrate. The well is located immediately downgradient of one of the DeRuyter Dairy's waste application fields.

The total nitrogen data show increasing concentrations from the upgradient well, past several sources of nitrogen, and to the downgradient wells. The downgradient wells contain substantially more nitrogen than is present in the upgradient well. The major ion concentrations, especially for calcium and chloride, increase between the dairy sources (dairy lagoons, dairy manure piles, and dairy application fields) and the downgradient wells with high nitrate. This pattern was also seen for barium and alkalinity.

For the organic compounds, four pesticides were detected in the water wells associated with the Dairy Cluster. However, none of these pesticides was detected in the dairy manure pile or dairy application field samples and as stated above the lagoon samples could not be quantified because of matrix interference problems.

Three trace organics were detected in water wells (DEHP, naphthalene, and tetrachloroethylene). Naphthalene and tetracycline were detected in a dairy supply well, while DEHP was detected in one downgradient well. Several of the trace organic compounds were found in all of the 12 dairy lagoons (for example, 3-beta-coprostanol; beta-sitosterol, and phenol).

For the wastewater pharmaceuticals, one water well had a detected level of DEET while there were three compounds detected in dairy lagoons (DEET; diphenhydramine; and thiabendazole). There were no detected levels in the dairy manure piles or application field samples.

Veterinary pharmaceuticals were detected in 10 water wells. Chlortetracycline was detected in one downgradient well, two dairy lagoons, and six manure pile or application field samples. Monensin was detected in two supply wells and two downgradient wells and in all but one of the dairy sources. Tetracycline was detected in the upgradient water well, two supply wells, and two downgradient wells and all of the dairy sources. Tylosin was detected in one downgradient well and several dairy sources while virginiamycin was detected in one supply well and two downgradient wells and several dairy lagoon samples.

Table 25: Dairy Cluster – Comparisons of Major Ions and Organic Compounds Detected in Samples from Wells and Dairy Operations and Assessment of Nitrate Sources in the Wells Using Isotopic Analyses

Residential Well Number	Nitrate Concentration (mg/L)[a]	General Chemistry in Well	Organic Compounds Detected in Well	Organic Compounds also Detected in Dairy Sources	Dominant Source(s) of Nitrate Based on Isotopic Analyses
WW-06 Upgradient Well	0.6	No trends in total nitrogen or major ions as this is an upgradient well	Atrazine, DEHP Tetracycline α-Estradiol testosterone	Not applicable. WW-06 is an upgradient well.	Not measured because lack of nitrate in sample
WW-10 Downgradient Well	Not Detected	No large trends in total nitrogen or major ions between WW-06 and WW-10	DEET Monensin	DEET (8 lagoons) Monensin (all the dairy sources except LG-07)	Not measured because lack of nitrate in sample
WW-11 Downgradient Well	21.6	Total nitrogen concentration increased 30-fold compared with the upgradient well Three to 25-fold increase in concentration of five major ions compared with the upgradient well.	DEHP Tetracycline Tylosin Testosterone	DEHP (LG-10) Tetracycline (all dairy sources) Tylosin (5 lagoons, 2 manure pile, and one application field sample) Testosterone (9 lagoons and one manure pile sample)	Fertilizer and/or animal waste
WW-12 Downgradient Well	43.6	Total nitrogen concentration increased more than 60-fold compared with the upgradient well Five to almost 20-fold increase in concentration of five major ions compared with the upgradient well.	Atrazine Androstadienedione Androsterone	Androstadienedione (three lagoons and 4 manure samples)	Fertilizer and/or animal waste

Residential Well Number	Nitrate Concentration (mg/L)[a]	General Chemistry in Well	Organic Compounds Detected in Well	Organic Compounds also Detected in Dairy Sources	Dominant Source(s) of Nitrate Based on Isotopic Analyses
WW-13 Downgradient Well	42.0	Total nitrogen concentration increased more than 60-fold compared with the upgradient well Six to more than 35-fold increase in concentration of five major ions compared with the upgradient well.	Alachlor Atrazine Ioxynil Virginiamycin	Virginiamycin (6 lagoons)	Animal waste
WW-14 Downgradient Well	40.7	Total nitrogen concentration increased almost 60-fold compared with the upgradient well. Two to almost 50-fold increase in concentration of six major ions compared with the upgradient well.	Atrazine Monensin	Monensin (All the dairy sources except LG-07)	Animal waste
WW-15 Downgradient Well	27.4	Total nitrogen concentration increased more than 40-fold between compared with the upgradient well. Two to more than 20-fold increase in concentration of six major ions compared with the upgradient well.	Atrazine Chlortetracycline Androsterone	Chlortetracycline (2 lagoons, all manure and application fields except SO-09 and SO-10)	Fertilizer and/or animal waste with some atmospheric contribution
WW-16 Downgradient Well	23.0	Total nitrogen concentration increased more than 30-fold compared with the upgradient well. Three to almost 30-fold increase in concentration of five major ions compared with the upgradient well.	Atrazine		Fertilizer and/or animal waste
WW-17 Downgradient Well	23.3	Total nitrogen concentration increased more than 30-fold compared with the upgradient well. Four to almost 30-fold increase in concentration of five major ions compared with the upgradient well.	Alachlor Atrazine DEHP Tetracycline Androsterone	DEHP (LG-10) Tetracycline (all dairy sources)	Fertilizer and/or animal waste

[a]Nitrate results are from Cascade Analytical Laboratory

ND – Not Detected

Four hormones were detected in either the upgradient well or downgradient water wells and in a dairy source. The hormone 17-α-Estradiol was detected in the upgradient well and in several of the dairy sources but not in the downgradient wells. Androstadienedione was detected in one supply well, one downgradient well, and several dairy sources. Androsterone was detected in one supply well and three downgradient wells but not in any dairy sources. The concentration of testosterone was higher in the upgradient well than in the one downgradient well where testosterone was detected. The majority of dairy lagoons had testosterone detections.

The isotopic analysis indicates that the dominant nitrogen source for two downgradient wells is animal waste (WW-13 and WW-14) while the dominant source for dairy supply well WW-07 is fertilizer. The other wells show a mixture of animal waste and fertilizer as a source. Wells WW-08 and WW-15 have some atmospheric nitrogen contribution in addition to animal waste and fertilizer.

In conclusion, all the downgradient residential water wells (with the exception of WW-10) associated with the Dairy Cluster have nitrate levels greater than the MCL. The data for total nitrogen and major ions indicate an increase in concentrations from the upgradient well to the downgradient wells, with the dairy lagoons, dairy manure piles, or dairy application fields likely sources. Barium and total alkalinity also show similar patterns.

Monensin and tetracycline were detected in the majority of dairy sources and in downgradient wells. Tetracycline was detected in two of the downgradient residential water wells and at a similar concentration in the upgradient well. It is possible that the dairies are sources of tetracycline, but given the concentration of tetracycline in the upgradient well was higher than the concentrations in the downgradient residential water wells, another source of tetracycline is likely. The dairy sources are a likely source of the monensin detected in the downgradient wells. These compounds were not detected in samples from the wastewater treatment plants influents, which suggests septic systems are not a likely source.

The hormone testosterone was detected in downgradient residential drinking water wells and dairy sources, although the concentration in the upgradient well is similar to the concentrations in the downgradient wells. It is possible that the dairies are a source of testosterone, but given the concentration of testosterone in the upgradient well, another source is likely.

C. Irrigated Cropland

Another likely source of nitrate in drinking water wells is nitrogen-rich fertilizers, such as inorganic synthetic fertilizer and manure applied to irrigated crops. As part of this study EPA looked at two fields each for three crops: mint, hops, and corn. EPA collected soil samples from six fields that were located upgradient from six residential drinking water wells which had been tested and found to exceed the MCL for nitrate. In each field, thirty soil subsamples at a depth of approximately one inch were collected and composited for analysis. Each downgradient water well and its associated soil sample is shown in Figure 11 and Table 26 along with the USDA NRCS soil type.

Table 26: Irrigated Cropland –Well Sample Locations and Associated Soil Samples, Crop Types and Soil Types

Water Well Sample	Associated Soil Sample	Crop Owner	Crop Type	USDA NRCS Soil Type
WW-23	SO-11	Schilperoort Farm	Mint	Warden Silty Loam
WW-24	SO-12	Havilah Farm	Mint	Warden Silty Loam
WW-25	SO-13	Wheeler Farm	Corn	Warden Silty Loam
WW-28	SO-14	Sunny Dene Ranch	Corn	Hezel Loamy Fine Sand & Cleman Very Fine Sandy Loam
WW-26	SO-15	Golden Gate Hops	Hops	Hezel Loamy Fine Sand
WW-27	SO-16	Golden Gate Hops	Hops	Warden Silty Loam

EPA contacted the cropland owners about crop history and fertilizer use. Information about the corn and mint fields is presented in Table 27; however, the hop field owners did not respond. All farmers stated that the application of fertilizer was determined by periodic crop or soil sampling. In addition, one of the corn field owners (SO-14) identified his field as an application field for waste from his dairy.

Table 27: Irrigated Cropland – Crop Field History and Fertilizer Use

Soil Sample ID	Current Crop	Crop Field History	Fertilizer History
SO-11	Mint	Planted with mint for past 23 years.	Synthetic fertilizer only.
SO-12	Mint	Planted with mint for past 4 years.	Mix of compost and synthetic fertilizer.
SO-13	Corn	Planted with corn for at least the past 5 years.	Synthetic fertilizer only.
SO-14	Corn	Planted with corn since 2010. Planted with alfalfa in 2008 and 2009. Planted with hops prior to 2008.	Manure in the fall and synthetic fertilizer during the growing season.
SO-15	Hops	No information was provided by the crop field owner.	No information was provided by the crop field owner.
SO-16	Hops	No information was provided by the crop field owner.	No information was provided by the crop field owner.

Soil types in the parcels selected for sampling in this study were from two USDA NRCS soil units. Warden soils are silt loams which are wind deposited silts, which lie on terraces of the Yakima River or on lake sediments deposited during the last glacial period. Warden soils are deep and well drained with little likelihood to retain nutrients which infiltrate beyond the root zone. Hezel soil is loamy fine sand. Hezel soils are formed in lacustrine sediment and have a mantel of eolian sand. Hezel soils are well drained with rapid permeability in the upper loamy fine sand part, dropping to moderately slow in the underlying stratified material. The rapid infiltration provides little opportunity for attenuation of any excess nutrients moving beyond the root zone. (See EPA 2012a for detailed soil reports for the six crops.)

The soil samples were analyzed for several forms of nitrogen, pesticides, pharmaceuticals, and hormones. They were not analyzed for major ions, trace inorganic elements, perchlorate, microbiology, trace organics, isotopic analysis, or age dating analysis.

1. IRRIGATED CROPLAND: GENERAL CHEMISTRY

Irrigated Cropland: Nitrate and Other Forms of Nitrogen

All of the water wells sampled downgradient of the irrigated cropland had nitrate levels greater than the MCL of 10 mg/L. Soil samples were analyzed for several forms of nitrogen, including extractable nitrate (nitrate-N), extractable ammonium (ammonia-N), and total nitrogen by combustion. Table 28 shows the measured values for these forms of nitrogen in these crop soils. If irrigation is applied above crop demand the levels of nitrate in the soils, if not reduced either by uptake by growing plants, volatilization, or denitrification, could ultimately move out of the root zone and become a source of groundwater contamination.

Table 28: Irrigated Cropland – Concentrations of Nitrogen in Soil Samples Collected From Mint, Corn, and Hop Fields Near Wells WW-23 to WW-28

Soil Sample/Crop	Nitrate-N (ppm)	Ammonium-N (ppm)	Total N by Combustion (ppm)
SO-11/Mint	245	210	3330
SO-12/Mint	191	8.2	2350
SO-13/Corn	24.3	7.5	1100
SO-14/Corn	6.3	12	1180
SO-15/Hops	83.5	21	2210
SO-16/Hops	26.5	7.7	3000

2. IRRIGATED CROPLAND: MICROBIOLOGY

There were no detections of total coliform, fecal coliform, or *E. coli* in the six water wells. The crop samples were not evaluated for microbiology.

3. IRRIGATED CROPLAND: ORGANIC COMPOUNDS

Irrigated Cropland: Pesticides

Atrazine and bentazon were the only pesticides detected in the water wells. Atrazine was detected in WW-24 and WW-26 and bentazon was detected in WW-23 and WW-24. Atrazine was not detected in any of the crop soil samples, while bentazon was detected in SO-11 (mint field) and SO-12 (mint field). Bentazon is used for selective control of weeds in beans, rice, corn, peanuts, and mint (ETN 1993). Bentazon was detected in two water wells and crop soil samples associated with each other (WW-23 and SO-11 and WW-24 and SO-12) (Table 29). This result indicates that the bentazon applied to the mint fields is likely migrating to groundwater and the water wells. Fifteen other pesticides were detected in crop soil samples, but not detected in the associated water wells (Table C9 in Appendix C).

Table 29: Irrigated Cropland – Concentrations of Atrazine and Bentazon in Wells WW-23 to WW- 28 and in Nearby Crop Soil Samples

Water Well and Soil Sample Location (Crop)	Concentration of Atrazine	Concentration of Bentazon
WW-23 SO-11 (Mint)	ND ND	0.028 (J) µg/L 38 µg/kg
WW-24 SO-12 (Mint)	0.017 (J) µg/L ND	0.033 (J) µg/L 2 (J) µg/kg
WW-25 SO-13 (Corn)	ND 1.6 (J) µg/kg	ND ND
WW-26 SO-15 (Hops)	0.025 (J) µg/L ND	ND ND
WW-27 SO-16 (Hops)	ND ND	ND ND
WW-28 SO-14 (Corn)	ND 0.7 (J) µg/kg	ND ND

J – the compound was positively identified, but the associated numerical value is an estimate.

Irrigated Cropland: Pharmaceuticals

There were no detections of wastewater pharmaceuticals in the water wells or the crop soil samples.

Nine veterinary pharmaceuticals were detected in one well (WW-26). Monensin was the only compound detected in a water well (WW-26 at 0.319 µg/L) and its associated soil sample (SO-15 at 4.5 µg/kg). The other compounds detected in water well WW-26 (erythromycin, lincomycin, ractopamine, sulfamethazine, sulfamethoxazole, sulfathiazole, tiamulin, and virginiamycin) were not detected in the associated crop soil sample. There were no detections of any veterinary pharmaceuticals in any of the other water wells.

Four veterinary pharmaceuticals were detected in the crop soil samples.

- SO-11: Oxytetracycline
- SO-12: Oxytetracycline
- SO-13: No detections
- SO-14: Oxytetracycline
- SO-15: Monensin, oxytetracycline, and tetracycline
- SO-16: Monensin, oxytetracycline, tylosin, and tetracycline.

Irrigated Cropland: Hormones

EPA's Ada Laboratory analyzed the six water well samples for five hormones (17-α-estradiol, 17-β-estradiol, estrone, 17-α-ethyl-estradiol and estriol). The laboratory did not detect any of the five hormones in the water wells.

The UNL Laboratory analyzed the water wells and associated soil samples for 20 hormones, including the five hormones that the EPA's Ada Laboratory analyzed. The UNL Laboratory detected six hormones in one well WW-27 (17-α-estradiol, androstadienedione, 17-β-trenbolone, androsterone, epitestosterone, and testosterone). These six compounds were not detected in the crop soil sample (SO-16) associated with WW-27. The UNL Laboratory did not detect any hormones in the other five water wells.

Five hormones were detected in crop soil samples (Table C14 in Appendix C).

- SO-11: Androstadienedione and progesterone
- SO-12: 4-androstenedione, 17-α-estradiol, and progesterone
- SO-13: Melengesterol acetate
- SO-14: No detections
- SO-15: 4-androstenedione, androstadienedione, and progesterone
- SO-16: 4-androstenedione and progesterone

4. IRRIGATED CROPLAND: ISOTOPIC ANALYSES

An isotopic analysis was performed for six wells associated with the irrigated croplands. Table 30 provides the results for these six wells. Additional details on the results of isotopic analyses conducted for this study are provided in Appendix D of this report.

The dominant source for WW-24 is fertilizer, while the dominant source for WW-27 is animal waste. For the other water wells, the potential sources are likely to be a combination of fertilizer and animal waste for WW-23, WW-25, and WW-26 and a combination of fertilizer and animal waste with some atmospheric contribution for WW-28.

Table 30: Irrigated Cropland - Concentration of Nitrate in Wells, Isotopic Signatures, and the Interpreted Dominant Source(s) of the Nitrate Based on Observed Values

Location	Nitrate-N (mg/L)[a]	δ^{15}N-NO_3 (‰)	δ^{18}O-NO_3 (‰)	Interpreted Dominant Source(s)[b]
WW-23 (Mint)	17.3	2.2	18.0	Fertilizer and/or Animal Waste
WW-24 (Mint)	14	-0.3	12	Fertilizer
WW-25 (Corn)	32.9	2.4	15	Fertilizer and/or Animal Waste
WW-26 (Hops)	15.1	7.5	6.3	Fertilizer and/or Animal Waste
WW-27 (Hops)	19.9	8.8	17	Animal Waste
WW-28 (Corn)	69.6	5.5	44	Fertilizer and/or Animal Waste with Some Atmospheric Contribution

[a]The nitrate concentrations are from the UNL isotopic analysis.

[b]Interpretation of dominant sources is based on the following:

- δ^{15}N-NO_3. Values less than 2.0 = dominated by synthetic fertilizer; values between 2.0 to 8.4 = undetermined mixture of synthetic fertilizer and/or animal waste; values greater than 8.4 = dominated by animal waste.
- δ^{18}O-NO_3 values greater than 20.0‰ provide evidence for some atmospheric contribution. δ^{18}O-NO_3 values below 20.0‰ could have an atmospheric contribution, but it becomes indistinguishable from other sources.

5. IRRIGATED CROPLAND: AGE DATING

The age dating data for the six wells associated with the irrigated crops is presented in Table 31. The values for the water wells are younger than for any other group of samples in the study. The reported ages may not correspond to when the water became contaminated.

Table 31: Irrigated Cropland – Results of Age Dating Analyses Performed for Wells Reported in Years Since the Water Infiltrated From the Surface to the Aquifer

Location	Sample Age	Duplicate Age	Average
WW-23 (Mint)	Over Value[a]	Over Value	NA
WW-24 (Mint)	14.8 (J)	15.8 (J)	15.3
WW-25 (Corn)	10.3	9.8	10.1
WW-26 (Hops)	12.8 (J)	11.8 (J)	12.3
WW-27 (Hops)	Over Value	14.3 (J)	14.3
WW-28 (Corn)	Over Value	Over Value	NA

[a]"Over Value" means that the sample contained more SF_6 than can be explained by equilibrium with modern air.
J – the analyte was positively identified, but the associated numerical value is an estimate.

6. IRRIGATED CROPLAND: SUMMARY OF RESULTS FOR RESIDENTIAL WELLS

Table 32 summarizes information on the nitrate concentrations in the water wells along with any organic compounds detected in the water wells and the associated crop soil samples and the dominant source of nitrate based on the isotopic analysis. No microbial contamination was found in the downgradient wells.

Bentazon and atrazine were the only pesticides detected in the water wells associated with the six crop field soil samples. Bentazon was detected in the soil samples associated with water wells at two sites: SO-11/WW-23 and SO-12/WW-24. Atrazine was detected in two of the wells, but not in the associated soil samples.

Nine veterinary pharmaceuticals were detected in one well (WW-26). Monensin was the only veterinary pharmaceutical detected in the associated soil sample (SO-15) which was collected from a hop field. There were no detections of any veterinary pharmaceuticals in the other five water wells. Three hormones were detected in one well (WW-27) but were not detected in the associated soil sample (SO-16). Of these three hormones, 17- β-trenbolone is a synthetic growth hormone used exclusively in beef cattle (not dairy cows), while the other two hormones are natural compounds. The source of the 17- β-trenbolone is unknown. There were no detections in any hormones in the other five water wells.

The isotopic data indicate that fertilizer is a dominant source of nitrate in water well WW-24 which is downgradient of a mint field. The dominant source of nitrate in water well WW-27 which is downgradient of a hops field is animal waste (human or non-human).

Table 32: Irrigated Cropland – Comparisons of Organic Compounds Detected in Samples from Wells and Croplands and Assessment of Nitrate Sources in the Wells Using Isotopic Analyses

Water Well Location	Nitrate Concentration in Wells (mg/L)[a]	Summary of Organic Compounds Detected in Water Wells	Associated Crop Location	Summary of Organic Compounds Detected in Wells and Associated Crop Fields	Dominant Source(s) of Nitrate in Wells Based on Isotopic Analyses
WW-23	16.0	Bentazon	SO-11 (mint)	Bentazon	Fertilizer and/or Animal Waste
WW-24	13.8	Atrazine Bentazon	SO-12 (mint)	Bentazon	Fertilizer
WW-25	33.4	No detects	SO-13 (corn)	Nothing to compare	Fertilizer and/or Animal Waste
WW-26	15.3	Atrazine, erythromycin, lincomycin, monensin, ractopamine, sulfamethazine, sulfathiazole, tiamulin, and virginiamycin	SO-15 (hops)	Monensin only compound also detected in soil sample	Fertilizer and/or Animal Waste
WW-27	19.8	17-a-estradiol, androstadienedione 17- β-trenbolone, testosterone, androsterone, and epitestosterone	SO-16 (hops)	These compounds were not detected in soil samples	Animal Waste
WW-28	71.2	No detects	SO-14 (corn)	Nothing to compare	Fertilizer and/or Animal Waste with Atmospheric Contribution

[a]Nitrate results are from Cascade Analytical Laboratory.

In conclusion, the nitrate levels in all the water wells associated with the crop samples were above the nitrate MCL. Bentazon and monensin were the only compounds detected in water wells and the associated crop soil samples. This finding suggests that bentazon and monensin detected in the crop field soil are likely migrating to groundwater and nearby water wells. Possible manure application to the hop field could account for the monensin detected in the downgradient residential well.

Some of the cropland soils are well drained and highly permeable. High nitrogen crops planted on such soils and especially those that utilize rill irrigation may pose a threat to the aquifer (see Appendix G, Figure 1).

D. Residential Septic Systems

Four residential water wells (WW-19, WW-20, WW-21, and WW-22) were identified to evaluate whether high nitrate concentrations could be coming from septic systems (Figure 11). These wells were selected because they are in residential areas served by septic systems, but are not located near dairies or crop fields. To conduct this evaluation, samples were collected from the wastewater entering the treatment plants located in Zillah (SP-01), Mabton (SP-02), and Toppenish (SP-03 and SP-04). Sample SP-04 was collected because additional sample volume was requested for SP-03 by EPA's Manchester Laboratory. Sample SP-04 was collected on a different day and was assigned a different sample number. The laboratory did not need the extra volume to supplement sample SP-03 so sample SP-04 was analyzed for the same compounds as SP-03. Samples SP-03 and SP-04 are not duplicate samples because they were collected at different times.

The treatment plant influent samples were collected to serve as surrogates for septic systems by providing a characterization and quantification of compounds that are found in rural septage. EPA recognizes that these WWTPs may receive substances that are not found in residential septic systems (for example they may also receive commercial and industrial waste streams). The WWTPs sampled serve rural communities and are sufficiently similar to residential septic systems for the purposes of this study. This approach was used to determine whether the compounds detected in wells with high nitrate concentrations in areas with a high density of septic systems are similar to the compounds detected in WWTP influent or whether these wells are affected by other sources.

Samples collected from the WWTPs were analyzed for the same compounds as the water well samples, excluding the analysis for nitrate, pesticides, perchlorate, and age dating (Table C2). Nitrate was not analyzed in the WWTP influent samples as there would be very little formation of nitrate from the organic nitrogen in the waste because of the low oxygen environment of the sewer system. EPA's Manchester Laboratory attempted to analyze the pesticides in the WWTPs influent samples. However, the laboratory reported that because of significant interferences from the large number of organic compounds present in the waste, the pesticide concentrations could not be quantified. Perchlorate and age dating analyses were not conducted because the influent was composed of water co-mingled from many sources.

Although four wells were selected for this evaluation, all of the residential wells were compared with the WWTP data to determine whether septic systems are a likely source of the nitrate found in any Phase 3 well in the study.

1. SEPTIC SYSTEMS: GENERAL CHEMISTRY

The WWTP influent samples were collected to serve as surrogates for septic system influent and to characterize compounds found in rural septic systems. While the major ions and trace elements were measured for the WWTP and water wells, the results are not summarized here as there are no upgradient wells that can be used to compare the results.

Septic Systems: Nitrate and other Forms of Nitrogen

The nitrate levels in the four water wells were all greater than the MCL of 10 mg/L. The water wells also were evaluated for different forms of nitrogen. Ammonium and TKN were not detected in any of these wells indicating all detectable nitrogen was in the form of nitrate. No analysis similar to that conducted for the Haak Dairy and Dairy Cluster is possible because no upgradient wells were sampled for comparison.

2. SEPTIC SYSTEMS: MICROBIOLOGY

As found with other water wells in the study, neither total coliform, fecal coliform nor *E. coli* were detected in the four selected water wells. The WWTP influent samples were analyzed for fecal coliform and *E. coli*. (Table C8 in Appendix C). As expected, very high concentrations of both fecal coliform and *E. coli* were found in the influent to the WWTPs. Samples were also analyzed using MST to identify the source of the fecal contamination. Three of the samples indicated human sources, while one sample indicated both human and ruminant sources.

3. SEPTIC SYSTEMS: ORGANIC COMPOUNDS

Septic Systems: Pesticides

Atrazine and bentazon were detected in one well (WW-20). There were no pesticides detected in the other three water wells (WW-19, WW-21, and WW-22).

EPA's Manchester Laboratory attempted to analyze the pesticides in the WWTPs influent samples; however, the laboratory reported that the WWTP sample matrix was too difficult to analyze because of significant interferences from the large number of organic compounds present in the waste. Therefore, the pesticide concentrations could not be quantified from the WWTP influent samples.

Septic Systems: Trace Organics

The trace organics analysis includes compounds such as caffeine, fragrances, and disinfectants, which would be expected to be found in domestic wastewater. Trace organics were not detected in any of the four selected water wells. For the entire study, four residential wells had detectable levels of DEHP. Thirty-seven trace organics were detected in the WWTP influents (Table C10 in Appendix C). Nineteen of the trace organics were detected in all of the WWTP influent samples. This indicates that trace organics are being used and can be found in wastewater entering WWTP, but with a few exceptions these compounds were not detected in residential water wells.

Septic Systems: Pharmaceuticals

No wastewater pharmaceutical compounds were detected in the four selected water wells. For the entire study one wastewater pharmaceutical (DEET) was detected in one residential water well. Nine wastewater pharmaceuticals compounds were detected in at least one WWTP influent sample, with six of the compounds detected in all three WWTP influent samples (acetaminophen, cotinine, DEET, ibuprofen, naproxen, and triclosan) (Table C11 in Appendix C). As with the trace organics, the wastewater pharmaceuticals were detected in the WWTP influent, but not in the residential water wells.

Table 33 shows the veterinary pharmaceuticals detected in three water wells and the WWTP influent samples. Water well WW-22 contained no detected veterinary pharmaceuticals.

Table 33: Septic Systems – Concentrations of Veterinary Pharmaceutical Detected in Wells and WWTP Influents

Compound	Wells[a]			WWTP Influent[b]		
	Units: µg/L					
	WW-19	WW-20	WW-21	SP-01	SP-02	SP-03
Erythromycin	ND	ND	0.11	ND	R	ND
Lincomycin	ND	ND	0.371	ND	R	ND
Monensin	1.62	ND	0.194	ND	R	ND
Ractopamine	ND	ND	0.079	ND	R	ND
Sulfamethazine	ND	ND	0.053	ND	R	0.086
Sulfamethoxazole	ND	ND	0.04	ND	0.106 (J)	0.662
Sulfathiazole	ND	ND	0.051	ND	R	ND
Tetracycline	ND	0.04 (J)	ND	0.55 (J)	ND	ND
Tiamulin	ND	ND	0.05	ND	R	ND
Virginiamycin	ND	ND	0.162	ND	R	ND

[a]Water well WW-22 had no detected veterinary pharmaceuticals.

[b]Sample SP-04 was not analyzed for veterinary pharmaceuticals.

J – the compound was positively identified, but the associated numerical value is an estimate.

ND – not detected.

R – the sample was unusable.

Three compounds were detected in the water wells and in at least one WWTP influent sample (sulfamethazine, sulfamethoxazole, and tetracycline). Eight compounds were detected in the water wells, but not in the WWTPs. Nine compounds were detected in WW-21. Water well WW-21 is surrounded by possible septic sources; it is also downgradient from several hop yards and at a greater distance, downgradient from several large dairies. The residents raise poultry and beef cattle. Many of the compounds detected in WW-21 were not found in the WWTP influent samples. The data suggest that septic systems are not the source of many of the compounds detected in this well.

For the entire study, four veterinary pharmaceuticals were detected in the WWTP influent samples with three of those also detected in one or more residential water wells: sulfamethazine (two water wells); sulfamethoxazole (one water wells); and tetracycline (five water wells). Sulfamethoxazole and tetracycline are used by humans and it is possible that septic systems could be a source of these compounds in the residential wells.

Septic Systems: Hormones

EPA's Ada Laboratory analyzed the four water well samples and the WWTP influent samples for five hormones (17-α-estradiol, 17-β-estradiol, estrone, 17-α-ethyl-estradiol and estriol). The laboratory did not detect any of the five hormones in the water wells, but detected three of the hormones in all three of WWTP influent samples (17-β-estradiol, estriol, and estrone) (Table C13 in Appendix C).

The UNL Laboratory analyzed samples from the same four water wells and the WWTP influent samples for 20 hormones, including the same five hormones as the EPA's Ada Laboratory (Table C14 in Appendix C). The UNL Laboratory detected 17-α-estradiol, 17-β-estradiol, and estrone in water well WW-22 along with several other compounds. Androsterone was the only other hormone detected in any of the four water wells (WW-20).

Table 34 shows the concentrations of the compounds detected in water wells WW-20 and WW-22 and the corresponding concentrations in WWTP influent samples. No hormones were detected in water wells WW-19 and WW-21.

Table 34: Septic Systems – Hormone Concentrations in Wells and WWTP Influents

Compound	WW-20	WW-22	SP-01	SP-02	SP-03
	(Units: µg/L)				
17-β-estradiol	ND	0.006 (UNL)	0.021 (Ada)	0.035 (Ada)	0.034 (Ada)
Estrone	ND	0.004 (UNL)	0.077 (Ada)	0.096 (Ada)	0.073 (Ada)
Estriol	ND	ND	1.030 (Ada)	0.863 (Ada)	0.640 (Ada)
17-α-estradiol	ND	0.005 (UNL)	0.263 (UNL)	ND	ND
Androsterone	0.004(J) (UNL)	ND	5.049(J) (UNL)	2.137(J) (UNL)	3.187(J) (UNL)
Androstadienedione	ND	0.003 (UNL)	0.255(J) (UNL)	0.614(J) (UNL)	14.1 (J) (UNL)
β-Zearalanol	ND	0.003 (UNL)	ND	ND	ND
Testosterone	ND	0.01 (UNL)	0.053 (UNL)	0.059 (UNL)	0.045 (UNL)
11-Keto Testosterone	ND	0.005 (UNL)	0.1 (UNL)	0.043 (UNL)	ND
Epitestosterone	ND	0.004 (UNL)	ND	0.06 (UNL)	ND

J – the compound was positively identified, but the associated numerical value is an estimate.

ND – not detected.

Androsterone was detected in water well WW-20 and in the three WWTP influent samples. Eight compounds were detected in water well WW-22. It is possible that septic systems are a source of several of the compounds found in WW-22 and the androsterone in WW-20. Many of these compounds are naturally produced by humans (for example 17-β-estradiol, estrone, estriol, androsterone, and testosterone). All of these compounds were detected in the WWTP influent samples.

For the entire study, 14 hormones were detected in WWTP influent samples with seven of those detected in residential water wells. Testosterone and androsterone were the most frequently detected hormones: testosterone in nine water wells and androsterone in four water wells. Given that both of these compounds are natural sex hormones, the septic systems are a possible source of the hormones detected in the residential water wells.

4. SEPTIC SYSTEMS: ISOTOPIC ANALYSIS

Isotopic analysis was performed for wells WW-19 to WW-22 by the UNL Laboratory. Table 35 provides the results for these four wells. Additional details on the results of isotopic analysis conducted for this study are provided in Appendix D of this report.

Table 35: Septic Systems – Concentration of Nitrate in Wells, Isotopic Signatures, and the Interpreted Dominant Source(s) of the Nitrate Based on Observed Values

Location	Nitrate-N (mg/L)[a]	δ^{15}N-NO_3 (‰)	δ^{18}O-NO_3 (‰)	Interpreted Dominant Source(s)[b]
WW-19	36.4	8.7	15.4	Animal Waste[c]
WW-20	15	6.3	52.9	Fertilizer and/or Animal Waste with Some Atmospheric Contribution
WW-21	36.5	7.7	12.2	Fertilizer and/or Animal Waste
WW-22	16.6	10	11.0	Animal Waste

[a]The nitrate concentrations are from the UNL isotopic analysis.

[b]Interpretation of dominant sources is based on the following:

- δ^{15}N-NO_3. Values less than 2.0 = dominated by synthetic fertilizer; values between 2.0 to 8.4 = undetermined mixture of synthetic fertilizer and/or animal waste; values greater than 8.4 = dominated by animal waste.
- δ^{18}O-NO_3 values greater than 20.0‰ provide evidence for some atmospheric contribution. δ^{18}O-NO_3 values below 20.0‰ could have an atmospheric contribution, but it becomes indistinguishable from other sources.

[c] Animal waste can be either human or non-human waste

The dominant source of nitrate for WW-19 and WW-22 appears to be animal waste (human or non-human). For WW-20 the dominant sources are likely a combination of synthetic fertilizer and/or animal waste with some atmospheric contribution for WW-20. The likely source of nitrate in well WW-21 is a combination of synthetic fertilizer and/or animal waste. The probable sources of nitrate for these water wells match the variety of land uses surrounding these highly scattered water wells.

5. SEPTIC SYSTEMS: AGE DATING

Table 36 provides the age dating results for the four selected water wells. There is a wide scatter of ages in the water wells, with age measurements ranging from 14.3 years to 44.3 years. As previously discussed, the age dating indicates the number of years since the water infiltrated from the surface to the aquifer, not the time that has elapsed since the water became contaminated. The method used in this study can determine the age of water up to about 40 years, or approximately 1970. Beginning in the 1960s, SF_6 concentrations in the environment began increasing as a result of its use in electrical equipment as a replacement for PCBs. Prior to 1970, atmospheric concentrations of SF_6 were generally below the analytical method detection limit. Ages older than 40 years are considered approximations.

Table 36: Septic Systems – Results of Age Dating Analyses Performed for Wells Reported in Years Since the Water Infiltrated from the Surface to the Aquifer

Location	Sample Age	Duplicate Sample Age	Average
WW-19	44.3 (J)	34.3 (J)	39.3
WW-20	14.3 (J)	14.3 (J)	14.3
WW-21	31.3	28.8	30.1
WW-22	29.3 (J)	29.3 (J)	29.3

J – the analyte was positively identified, but the associated numerical value is an estimate.

6. SEPTIC SYSTEMS: SUMMARY OF RESULTS FOR RESIDENTIAL WATER WELLS

Table 37 summarizes the nitrate concentrations for the four water wells along with a summary of the organic compounds detected in both the four water wells and the WWTP influents. The dominant sources of nitrate based on the isotopic data are also included in Table 37. Although microbial contamination is often observed in situations where septic systems contaminate residential wells, no microbial contamination was found in the downgradient wells. There appears to be a correlation between the age dating data and the well depths for those water wells that have well depth information (see Appendix A3). Older water suggests a deeper well.

All four water wells had nitrate concentrations greater than the nitrate MCL. These four water wells were sampled in isolation – that is, without a pairing with an upgradient well with a specific source separating them. For this reason, no chemical or temporal evolution along a flow path can be demonstrated from these data.

The pesticides atrazine and bentazon were detected in WW-20; however, the WWTP influent samples could not be analyzed for pesticides because of matrix interference so there are no wastewater data with which to compare these results.

There were no detections of any trace organics for the water wells selected for the septic systems. WWTP influent had detections of multiple trace organics. Nineteen of the trace organics were detected in all of the WWTP influent samples.

Table 37: Septic Systems – Comparisons of Organic Compounds Detected in Wells and WWTP Influent, and an Assessment of Dominant Source(s) of Nitrate in the Wells Based on Isotopic Analyses

Sample Location	Nitrate Concentration in Water Wells (mg/L)[a]	Summary of Organic Compounds Detected in Well	Summary of Organic Compounds Detected in Well and WWTPs Influent	Dominant Source of Nitrate Based on Isotopic Analyses
WW-19	38.2	Monensin	None.	Fertilizer and/or Animal Waste
WW-20	15	Atrazine and bentazon Tetracycline Androsterone	(Atrazine and bentazon not analyzed) Tetracycline (SP-01) Androsterone (All WWTPs)	Animal Waste and/or Fertilizer with Some Atmospheric Contribution
WW-21	38	Sulfamethazine Sulfamethoxazole Erythromycin, lincomycin, monensin, ractopamine, sulfathiazole, tiamulin, and virginiamycin	Sulfamethazine (SP-03) Sulfamethoxazole (SP-02 and SP-03) Other organics detected in wells were not detected in WWTP influents	Fertilizer and/or Animal Waste
WW-22	16.4	11-keto testosterone 17-β-estradiol 17-α-estradiol Androstadienedione β-zearalanol Estrone Testosterone Epitestosterone	11-keto testosterone (SP-01and SP-02) 17-α-estradiol (SP-01) Androstadienedione (All WTPs) Testosterone (All WWTPs) Epitestosterone (SP-02)	Animal waste

[a]Nitrate results are from Cascade Analytical Laboratory

No wastewater pharmaceuticals were detected in the four water wells, while several of the wastewater pharmaceuticals were detected in the WWTP influent samples. Three water wells had veterinary pharmaceuticals detected. Water well WW-21 had nine detected compounds. Veterinary pharmaceuticals that were detected in the water wells and one or more WWTP influent samples were sulfamethazine (WW-21 and SP-03), sulfamethoxazole (WW-21 and SP-02 and SP-03), and tetracycline (WW-20 and SP-01).

Eight hormones were detected in water well WW-22 and each of those hormones was detected in one or more WWTP influent samples, except for β-Zearalanol. All of these hormones can be produced naturally by many different animals, and the detections in the water well could therefore arise from a variety of sources.

The isotopic data indicate that the dominant source of nitrate for WW-19 and WW-22 is animal waste (human or non-human) while the dominant sources for WW-20 is a combination of fertilizer, animal waste and/or atmospheric. The dominant source for WW-21 is fertilizer and/or animal waste.

In conclusion, the four water wells had nitrate levels greater than the MCL of 10 mg/L. Drinking water well WW-21 had nine pharmaceuticals detected, is surrounded by possible septic sources, and the family raises cattle and poultry on their parcel. Well WW-21 is also downgradient from several hop yards and at a greater distance downgradient from a dairy. Well WW-22 is not in close proximity to a current livestock operation. It is also possible that the detections for WW-22 are from a septic system.

E. Water Wells WW-18 and WW-30

Two other residential water wells were evaluated: WW-18 and WW-30. These water wells were not in the original study design. Water well WW-18 was sampled because the owner was aware of the study and volunteered his property for sampling. Water well WW-30 was sampled because it is located in an area not otherwise sampled, was high in nitrate, and the homeowner was willing to participate in the study.

Water well WW-18 was analyzed for all the compounds, including an isotopic and age dating analysis. Sample WW-30 was not evaluated for hormones, pharmaceuticals, isotopic, or age dating as the location was added later in the study. The summary results for the two wells are included in Table 38.

Table 38: WW-18 and WW-30 – Summary of Results Related to Nitrate Concentrations, Microbiology Evaluation, Detected Organic Compounds, Isotopic Analysis, and Age Dating Analysis

Compounds	WW-18	WW-30
Nitrate[a]	72.2 µg/L	23.4 µg/L
Microbiology	No detects	No detects
Organic Compounds	Atrazine, tetracycline, and testosterone	Atrazine, bentazon, and phenol
Isotopic Analysis	Fertilizer and/or Animal Waste with Some Atmospheric Contribution	Not conducted
Age Dating	28.1 years	Not conducted

[a]Nitrate results are from Cascade Analytical Laboratory

While the major ions and different nitrogen forms were measured for both of these samples, the results are not included here as there were no upgradient wells or potential sources sampled that could be used for comparison.

Neither fecal coliform nor *E. coli* was detected in the WW-18 or WW-30. Atrazine, tetracycline, and testosterone were detected in WW-18. Atrazine, bentazon, and phenol were detected in WW-30. Phenol was abundant in the dairy lagoons sampled and can also be found in household wastewater. Sample WW-30 is not located in the vicinity of a dairy. Sample WW-30 was not analyzed for wastewater pharmaceuticals because of its late addition at the end of the study.

X. STUDY LIMITATIONS AND UNCERTAINTIES

Several limitations in the study are important to note. First, water well samples were collected from existing wells. No new wells were installed for this study. Information on the depths and screened intervals of the water wells is known for about a third of the wells that were sampled. In this report, designations of upgradient and downgradient are based on regional groundwater flow data from the USGS. Lack of complete well information limits our ability to verify if the wells upgradient and downgradient of the sources draw water from the same water bearing zone.

A discussion of the QA/QC procedures and a summary of the data validation process are presented in Appendix E. Uncertainties and limitations with analytical data were noted in Appendix E and described in detail in the data validation memoranda. Data usability is also indicated in the data summary tables by inclusion of data qualifiers.

In addition, EPA lacks complete information regarding the dairies in this study. EPA requested information on specific aspects of the dairy operations and the physical setting; however, the dairies in this study did not provide this information. This information would have contributed to a more complete understanding of the dairy facilities, practices, and use of specific chemicals. It would have allowed EPA to provide actual values, or narrower ranges of estimates, for certain parameters in this report (for example, numbers of animals, quantities of nitrogen, estimates of lagoon leakage). EPA has, however, referenced general information regarding dairy operations, and specific information regarding the dairies in the study to the extent it was available.

Finally, EPA has limited information about the irrigated crop fields in this study. Verifiable, detailed crop production data, in terms of nutrients applied (the likely source of nitrate associated with irrigated crops), were not available and no irrigation data were available. EPA has included information about the crop fields to the extent it was available. In addition, the irrigated crop fields are surrounded by similar agricultural uses, and many are situated downgradient of dairies, making more difficult EPA's ability to discern the source of nitrate in drinking water wells downgradient of the irrigated crop fields.

XI. CONCLUSIONS

Nitrate levels above EPA's drinking water standard in residential drinking water wells in the Lower Yakima Valley are well documented. The objective of this study was to evaluate the effectiveness of certain chemicals, microbial parameters, or analytical techniques to identify specific sources of the high nitrate levels detected in residential drinking water wells.

Many of the chemicals and microbial parameters evaluated in this study were not detected in the residential drinking water wells. There were no detections of fecal coliform in the residential drinking water wells, although high concentrations were found in the dairy sources and WWTP influent. There were very few trace inorganic elements, trace organics, or wastewater pharmaceuticals detected in the residential drinking water wells or crop field soil samples, although many of these chemicals were detected in the dairy sources and WWTPs. The isotopic data provide some indication of the likely nitrate sources for seven of the 25 residential wells tested (six animal waste and one synthetic fertilizer). Although the isotopic analysis identified animal waste as the source of the nitrate in six wells, this analytical technique cannot differentiate between human and non-human waste.

There appears to be a correlation between the age dating data and the depths of the wells for which boring logs are available. The water in the dairy supply wells that are known to be screened in the deeper basaltic aquifer is older than in the downgradient residential wells which are commonly screened in the shallower alluvial aquifer. The age dating results were not useful to determine when the nitrate contamination was introduced into the well.

Haak Dairy

There are large quantities of nitrogen-rich materials on the Haak Dairy that could serve as sources of nitrate in groundwater and residential drinking water wells. The dairy lagoons are likely leaking nitrogen-rich wastewater into the underlying soils. Also, WSDA inspection reports show that the Haak Dairy has reported elevated nitrogen levels in some of their application fields. This poses a threat to groundwater because irrigation water or precipitation can carry excess nitrogen through the soil and into the aquifer. The prevalence of highly permeable surface soils at the Haak Dairy increases the risk of nitrogen migrating past the crop root zone to the aquifer resulting in groundwater contamination.

All three residential drinking water wells downgradient of the Haak Dairy that were sampled have nitrate levels greater than the MCL. Samples collected at the Haak Dairy show that the concentrations of total nitrogen and several of the major ions increase between the upgradient and downgradient wells, with the highest concentrations detected in the samples collected from the dairy lagoons, dairy manure pile, and dairy application fields. Barium, zinc and alkalinity show a similar pattern. These data indicate that the Haak Dairy is a likely source of the nitrate contamination in the three downgradient residential drinking water wells. Inorganic fertilizer used on the Haak Dairy's application fields also could be a source of nitrate observed in the downgradient wells.

Two pharmaceuticals, tetracycline and monensin, were detected in all of the dairy source samples collected at the Haak Dairy, indicating that these compounds are used by the dairy. Tetracycline was detected in two of the three downgradient residential water wells, but not in the upgradient well, indicating the Haak Dairy is a likely source.

Monensin was detected in the upgradient well and in the three downgradient residential water wells, although the upgradient residential drinking water well had a higher concentration than two of the downgradient wells. It is possible that the Haak Dairy is a possible source of the monensin detected in the downgradient residential drinking water wells. Given the presence of monensin in the upgradient well, another source of monensin is likely. Additional information that supports that the dairy source is a

possible source of monensin is that it was not detected in samples collected from the WWTP influents that were collected as surrogates for rural septic systems.

The isotopic data provide strong evidence that animal waste (human or non-human) is the likely dominant source of the nitrate contamination in at least one of the residential water wells (WW-05) downgradient of the Haak Dairy. However, since isotopic analysis cannot differentiate between human and non-human waste, both could be sources of the nitrate in the downgradient well. Isotopic data for the other two residential drinking water wells downgradient of the Haak Dairy indicate that the source of the nitrate could be animal waste, fertilizer, derived from the atmosphere, or some combination of these sources.

Several other compounds that tend to be less mobile in groundwater were detected in the Haak Dairy lagoon, manure pile, and application field samples, but not detected in the downgradient water wells (for example trace organics and hormones). Fecal coliform was not detected in any of the wells downgradient of the Haak Dairy.

Dairy Cluster

Similar to the Haak Dairy, the Dairy Cluster has large quantities of nitrogen-rich materials that could serve as sources of the nitrate found in the groundwater and residential drinking water wells. The lagoons at the Dairy Cluster are likely leaking nitrogen-rich wastewater into the underlying soils. WSDA inspection reports show that the Dairy Cluster dairies have reported elevated nitrogen levels in some of their application fields. This poses a threat to groundwater because irrigation water or precipitation can carry excess nitrogen through the soil and to the aquifer.

Similar to the Haak Dairy, the results from the sampling indicate that the concentration of total nitrogen and several of the major ions increase between the upgradient and downgradient wells, with the highest concentrations detected in the samples collected from the dairy lagoons, dairy manure piles, and dairy application fields. Barium and alkalinity showed a similar pattern. These data indicate the Dairy Cluster is a likely source of the nitrate contamination in the downgradient residential drinking water wells.

The pharmaceuticals tetracycline and monensin were detected in all but one of the dairy sources samples, which indicates they are used by the dairies at the Dairy Cluster. Tetracycline was detected in two of the downgradient residential drinking water wells, two dairy supply wells, dairy lagoons, manure pile, and application fields. The concentration of tetracycline in the upgradient well was similar to the concentrations detected in the two downgradient residential wells. The dairies are a possible source of the tetracycline in the downgradient residential water wells. However, given the concentration in the upgradient well, another source of the tetracycline likely exists.

Monensin was detected in two of the downgradient residential water wells, two dairy supply wells, dairy lagoons, manure piles, and application fields. The Dairy Cluster is a likely source of monensin because this antibiotic is used in dairy cows but not people. Monensin was not detected in samples from the WWTP influent samples that were collected as surrogates for residential septic systems, providing further support that the dairies are a likely source.

The hormone testosterone was detected in downgradient residential drinking water wells and dairy sources. The concentration of testosterone detected in the upgradient residential water well is similar to

the concentrations detected in the downgradient water wells. The dairies are a possible source of the testosterone in the downgradient wells; however, given the concentration in the upgradient well, another source for the testosterone is likely.

The isotopic data provide strong evidence that animal waste (human or non-human) is the likely dominant source of the nitrate in at least two of the residential water wells downgradient of the Dairy Cluster. Because isotopic analysis cannot differentiate between human and non-human waste, both could be sources of the nitrate in these downgradient wells. Isotopic data for the other residential drinking water wells downgradient of the Dairy Cluster indicate that the source of the nitrate could be animal waste, fertilizer, or derived from the atmosphere, or some combination of these sources.

Several other compounds that are generally less mobile in groundwater than nitrate and some of the major ions, were detected in the Dairy Cluster sources (for example, the trace organics), but not in the downgradient residential water wells. Fecal coliform was not detected in any of the residential water wells.

Given the historic and current volumes of wastes generated and stored by dairies, and the application of nitrogen-rich fertilizers including dairy waste in the Lower Yakima Valley, it is expected that dairies are a likely source of high nitrate levels in downgradient drinking water wells. The total nitrogen, major ions, alkalinity and barium data provide strong evidence that the dairies evaluated in this study are likely sources of the high nitrate levels in the drinking water wells downgradient of the dairies. Additional information that supports this conclusion includes: there are few potential sources of nitrogen located upgradient of the dairies; the dairy lagoons are likely leaking large quantities of nitrogen-rich liquid into the subsurface; and Washington State Department of Agriculture inspectors have reported elevated levels of nitrogen in application fields of the dairies in the study.

Irrigated Cropland

Nitrogen-rich fertilizers, such as inorganic synthetic fertilizer and manure, are applied to irrigated crop fields and are a possible source of nitrate in drinking water wells. In Phase 3, EPA sampled six irrigated crop fields (two mint, two hops, and two corn) and six residential water wells downgradient of these fields**.** The six water wells downgradient from the irrigated crop fields and sampled by EPA during Phase 3 all had nitrate levels greater than the MCL. Several organic compounds were detected in the crop soil samples but only bentazon and monensin were detected in a water well and its associated crop field soil sample. Bentazon was detected in two water wells and the associated mint field soil samples. These results indicate that bentazon was applied to the crop field and is likely migrating to the groundwater and water wells. Monensin was the only veterinary pharmaceutical detected in one well and also in an associated soil sample collected from a hop field. Possible manure application to the hop field could account for the monensin detected in the downgradient residential well.

The isotopic data provide strong evidence that synthetic fertilizer is a dominant source in one residential drinking water well downgradient of a mint field and that animal waste (human and non-human) is a dominant source of the nitrate in one well downgradient of a hops field. Isotopic analysis cannot differentiate between human and non-human waste. Isotopic data for the other residential drinking water wells downgradient of the crop fields indicate that the source of the nitrate could be animal waste or fertilizer, with some contribution from the atmosphere.

Given the historic and current application of nitrogen-rich fertilizers in the Lower Yakima Valley, it is expected that irrigated crop fields would be a likely source of high nitrate levels in downgradient drinking water wells. The data collected in this study provide some corroboration that irrigated crop fields are a likely a source of nitrate in groundwater. The data supporting this conclusion is not as strong for the crop fields as it is for the dairies. The reasons for this include: lack of upgradient well data; the irrigated crop fields sampled are situated amongst other agricultural uses, including upgradient dairy operations; fewer analytes detected in both the crop field samples and the corresponding downgradient wells; more limited information about crop field operations; and the crop fields' positions on the landscape relative to other potential sources.

Residential Septic Systems

Four residential water wells were identified for evaluation of impacts from septic systems. However, all of the residential drinking water wells sampled as part of Phase 3 of this study were analyzed for the same suite of chemicals. Although all the residential water wells were evaluated to determine if septic systems could be a likely source of the nitrate in water wells, the four wells identified to evaluate the potential contribution from septic systems were selected because they are in residential areas served by septic systems, but are not located near dairies or crop fields. EPA also collected influent samples from three WWTP located in Zillah, Mabton, and Toppenish.

The WWTP influent had no actual or potential hydrogeological connection with the residential wells. These treatment plant influent samples were collected to serve as surrogates for septic systems by providing a characterization and quantification of compounds that are found in rural septage, while recognizing that these WWTPs also may receive commercial or and industrial waste streams. The WWTP and residential drinking water well data were compared to determine whether the drinking water wells contained the same compounds as the WWTP influent samples which could indicate that the septic systems are a source of nitrate in the residential drinking water wells.

The majority of the trace organics (for example personal care products) and wastewater pharmaceuticals were detected in the WWTP influent samples, but only two of these compounds were detected in the residential drinking water wells sampled by EPA in Phase 3. Specifically, DEHP was detected in four residential drinking water wells and DEET was detected in one residential water well. This indicates the trace organics are being used and can be found in wastewater, but with a few exceptions are not reaching residential drinking water wells.

Four veterinary pharmaceutical compounds were detected in the WWTP influent samples, three of which were also detected in one or more residential water wells. Specifically, sulfamethazine (used for cattle, poultry, and swine) was detected in two residential water wells, sulfamethoxazole (used for people) in one residential drinking water well, and tetracycline (used for people, cattle, and several other animals) in six residential drinking water wells.

There were 10 additional veterinary pharmaceuticals detected in residential water wells, but not detected in WWTP influent samples. Monensin (used for cattle and poultry) and virginiamycin (used in poultry and swine) were the most frequently detected veterinary pharmaceuticals: monensin was detected in nine residential water wells and virginiamycin in four. Monensin and virginiamycin were not detected in the

WWTP influent samples. Given the results, septic systems are a possible source of tetracycline and sulfamethoxazole, both of which can be used by humans, in the residential drinking water wells.

Of the 20 hormones analyzed, 14 were detected in at least one WWTP influent sample. Of those 14 hormones, seven were detected in residential water wells. Testosterone and androsterone were the most frequently detected hormones: testosterone was detected in nine wells and androsterone was detected in four wells. Given both testosterone and androsterone are natural sex hormones it is possible they came from septic systems in proximity to the residential water wells, but these compounds were also detected in wells downgradient of the dairies.

While the septic systems could be a source of nitrate in drinking water wells, there is insufficient information from this study to support this conclusion.

The high nitrate levels in residential drinking water wells in the Lower Yakima Valley are likely coming from several sources. This study attempted to identify those sources. In some cases it was possible to identify likely or possible sources of the nitrate contamination.

Evaluating actions to reduce nitrate concentrations in residential drinking water wells to safe levels is beyond the scope of this report. Although actions to reduce nitrate are needed, it may take many years to reduce the nitrate levels in residential drinking water wells to safe levels because of the extent of the nitrate contamination in the Lower Yakima Valley and the persistence of nitrate in the environment.

[a]Phase 3 nitrate concentrations reported by Cascade Analytical Laboratory.

Figure A1: Phase 3 - Relationship Between Water Well Depth and Nitrate Concentrations

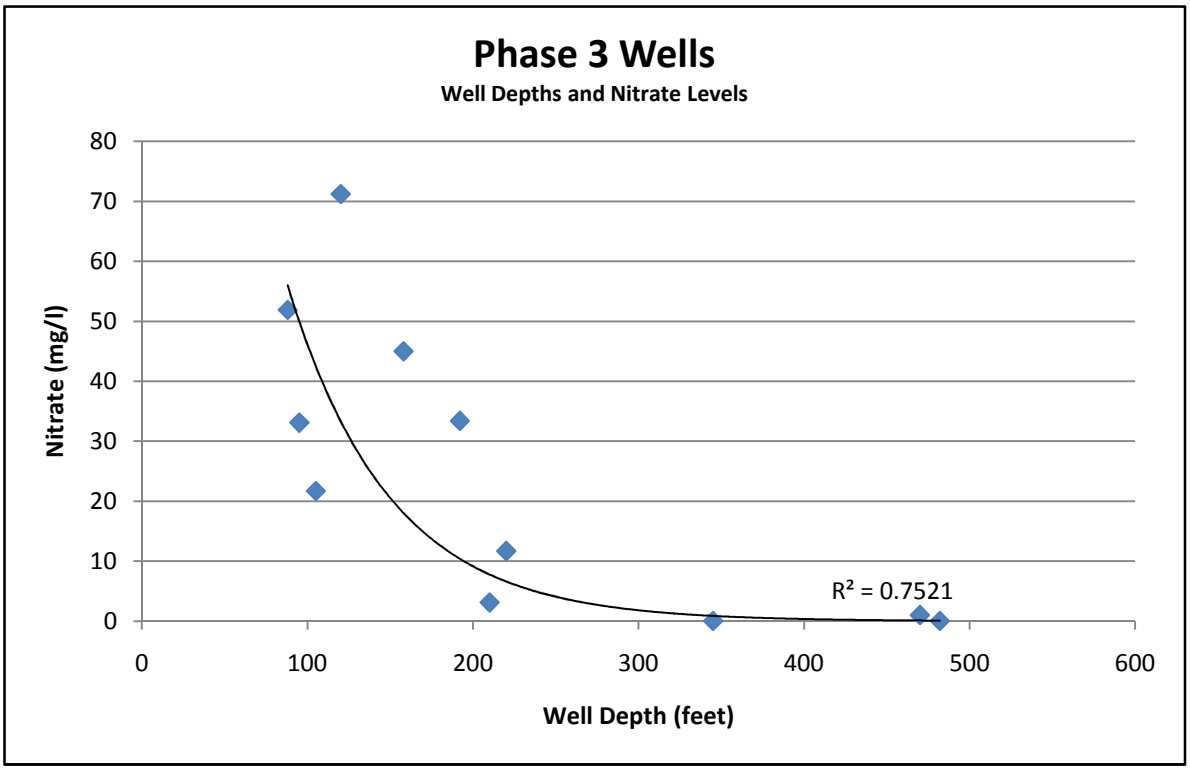

Figure A1 Supporting Data

EPA Phase 3 Well Number	Well Depth from WADOE Well Report (Total Depth)	Nitrate (mg/l)	Well Completed in Alluvial Aquifer or in Basalt	Well Type
WW-04	88	51.9	Alluvial	Domestic
WW-03	95	33.1	Alluvial	Domestic
WW-17	105	21.7	Alluvial	Domestic
WW-28	120	71.2	Unknown	Domestic
WW-12	158	45	Alluvial	Domestic
WW-25	192	33.4	Alluvial	Domestic
WW-02	210	3.12	Basalt	Dairy/Domestic
WW-08	220	11.7	Alluvial	Dairy
WW-10	345	0.05	Alluvial	Domestic
WW-07	470	1.02	Basalt	Dairy
WW-09	482	0.05	Basalt	Dairy

Notes:

Well logs are probable matches based on available information.

WW-28 information based on well owner interview.

The WW-02 well log may be for one of two wells that feed into the Haak dairy water supply.

"Well Type" is based on EPA's understanding of the current use of the well.

WADOE = Washington State Department of the Ecology

WW-07	34.6	470
WW-09	54.8	482

Notes:
Water in wells WW-09 and WW-10 may be older than indicated.

APPENDIX B
SURFACE SOIL CHARACTERISTICS OF THE STUDY AREA

(This page intentionally left blank.)

Appendix B: Surface Soil Characteristics of the Study Area

Surface soils in Yakima County have been characterized and mapped by the Natural Resources Conservation Service (NRCS 2012). A soil report was generated from the NRCS database for each dairy and irrigated crop field in the study and EPA compiled the soil reports (EPA 2012). A summary of surface soil characterization for each of the dairies and irrigated crop field is presented below.

HAAK DAIRY

Within the Haak Dairy property boundary, five soil units have been mapped by the NRCS. All five soil units have a silt loam texture with a "well-drained" classification. Three of the soil units (Scooteney, Sinloc, and Warden) represent 82 percent of the surface area. They have a saturated hydraulic conductivity in the range of 1.1 to 4.0 feet per day, which is characterized as "moderately high to high" in their capacity to transmit water. Saturated hydraulic conductivity is a measure of soil permeability and describes how quickly water moves through soil under saturated conditions. Likewise the other two soil units (Burke and Scoon) have a moderately high to high capacity to transmit water to a depth of 2 to 3 feet below ground surface; however, a cemented layer is present below this depth with a saturated hydraulic conductivity in the "very low to moderately low" range of 0.0 to 0.10 feet per day. The Burke and Scoon units are located in the northwest portion of the Haak Dairy property and account for 18 percent of the surface area.

DAIRY CLUSTER

Almost all the surface soils underlying the Dairy Cluster have a "well drained" classification, which means water moves readily through the soil.

More than 80 percent of the surface soils underlying the Dairy Cluster are highly permeable. Highly permeable is defined here to mean having a high hydraulic conductivity. The prevalence of highly permeable surface soils is significant because it increases the risk of groundwater contamination due to water carrying nitrogen into the ground more readily than if the soils were of lower permeability.

Within the approximate boundary of the Liberty Dairy and Bosma Dairy, 10 soil units have been mapped by NRCS. Most all of them are characterized by a silt loam texture and are classified as "well drained", except for two (Outlook and Sinloc) which have a "somewhat poorly drained" classification. Six of the soil units (Outlook, Scooteney, Shano, Sinloc, Warden, and Esquatzel) represent approximately 87 percent of the surface area. The soil units have a saturated hydraulic conductivity in the range of 1.1 to 4.0 feet per day, which is characterized as "moderately high to high". Three of the soil units (Burke, Moxee, and Scoon) have a saturated hydraulic conductivity in the range of 0.0 to 0.10 feet per day, which is characterized as "very low to moderately low." One of the soil units (Finlay) has a saturated hydraulic conductivity of 1.98 to 5.95 feet per day, which is characterized as "high".

Within the approximate property boundary of the Cow Palace, six soil units have been mapped by the NRCS. All six soil units have a silt loam texture with a "well-drained" classification. Three of the soil units (Esquatzel, Shano, and Warden) represent approximately 81 percent of the surface area. These units have a saturated hydraulic conductivity in the range of 1.1 to 4.0 feet per day, which is characterized as "moderately high to high" in their capacity to transmit water. Two of the soil units (Burke and Scoon) represent approximately 19 percent of the surface area and have a saturated hydraulic conductivity in the range of 0.0 to 0.12 feet per day, which is characterized as "very low to moderately low." One of the soil

units (Finlay) represents less than 1 percent of the surface area and has a saturated hydraulic conductivity of 4 to 11.9 feet per day, which is characterized as "high."

Within the approximate boundary of the DeRuyter Dairy and the D and A Dairy, five soil units have been mapped by the NRCS. All five soil units have a silt loam texture with a "well drained" classification. Three of the soil units (Scooteney, Esquatzel, and Warden) represent 92 percent of the surface area. They have a saturated hydraulic conductivity in the range of 1.1 to 4.0 feet per day, which is characterized as "moderately high to high" in their capacity to transmit water. One of the soil units (Scoon) represents approximately 7 percent of the surface area, and has a saturated hydraulic conductivity of 0.0 to 0.12 feet per day, which is described as "very low to moderately low." Another soil unit (Finley) represents just over 1 percent of the land surface area and has a saturated hydraulic conductivity in the range of 4.0 to 11.9 feet per day, which is described as "high."

Irrigated Crop Fields

There were six crop fields sampled in this study: two mint fields (soil samples SO-11 and SO-12); two corn fields (soil samples SO-13 and SO-14); and two hop fields (soil samples SO-15 and SO16). Soil samples SO-11, SO-12, and SO-13 were collected from the same type of soil unit – Warden - which is classified as being "well drained" with a saturated hydraulic conductivity in the range of 1.1 to 4.0 feet per day, which is characterized as "moderately high to high".

Soil sample SO-14 is composed of three soil units – Cleman, Hezel, and Warden. The Cleman unit is well drained and is characterized as having a saturated hydraulic conductivity of "moderately high to high." The Hezel is classified as being "somewhat excessively drained" with a "moderately high" saturated hydraulic conductivity. The Warden soil is also "somewhat excessively drained" with a "moderately high to high" saturated hydraulic conductivity.

Soil sample SO-15 is composed of three soil units – Esquatzel, Hezel, and Warden. The Esquatzel and Warden units are classified as well drained with a "moderately high to high" saturated hydraulic conductivity. The Hezel soil unit is classified as being "somewhat excessively drained" with a "moderately high" saturated hydraulic conductivity.

Soil sample SO-16 is composed of two soil units – Esquatzel and Warden. Both of these units are classified as well drained with a "moderately high to high" saturated hydraulic conductivity.

Units

mg/L = milligrams per liter

Data Qualifiers

J = The analyte was positively identified. The associated numerical value is an estimate.

U = The analyte was not detected at or above the reported value.

< = The level of the target organism present in the sample is less than the detection limit. The reported value is the detection limit.

> = The level of the target organism present in the sample exceeds the upper limit for microbial estimates. The reported value is the

Table C1: Phase 2 Field Measurements and Laboratory Analytical Results

Location ID	Sample ID	Sample Type[a]	Compound	Result	Qualifier	Units	Analytical Method

Notes:

[a]Samples submitted to the laboratory were analyzed by the EPA Manchester Environmental Laboratory.

[b]Sample No. 10096334 was submitted to the laboratory for microbial source tracking (MST) analysis. Results are presented below.

Biomarker	Result
BAC-32	Present
CF-128	Absent
CF-193	Absent
MST-	General Bacteriodes Present
HF-183	Absent
HF-134	Absent

BAC32: This is the screening Bacteroides biomarker. If it is present, further testing is done to determine the specific source. If the test is negative, nothing more is done.

CF128 and CF193: These are two separate biomarkers that identify the presence of ruminant fecal source. Between the two of them, they comprise most of the biomarkers that would be found in ruminants. There may be other biomarkers that could exist in very isolated populations of ruminants, but these two will identify the majority. A "P" would identify detection of the biomarker in the particular sample, an "A" indicates absence of that biomarker in the sample.

HF134 and HF183: These are two separate biomarkers that identify the presence of human fecal source. As above, between the two of these biomarkers, the majority of human source will be detected. Again, a very isolated community might develop a different biomarker. A "P" would identify detection of the biomarker in the particular sample, an "A" indicates absence of that biomarker in the sample.

MST- Microbial Source Tracking. MST contaminants: This identifies by two letter code the kind of fecal source was identified in the particular sample.GB indicates that although Bacteroides DNA was present, the source was neither human nor ruminant. An "A" indicates that no Bacteroides DNA was present in the sample. H indicates human source; R indicates ruminant; H/R indicates that both were found in that sample. To be noted, where there is a species identification, there may be fecal contamination from other species present as well, but due to method limitations is not identified.

Abbreviations

NA- Not applicable

Notes

[1]The other nitrogen compounds evaluated included: total Kjeldahl Nitrogen (TKN); extractable nitrate, extractable ammonia and total nitrogen by combustion.

[2]Lagoon samples were evaluated but it was determined that because of matrix interferences it was not possible to reliably quantify the compounds..

[3]The specific analysis depended on which laboratory analyzed the sample. The analysis included either total coliform, fecal coliform, and/or E Coli. Microbial source tracking was performed for 9 lagoons and all wastewater treatment plant influent samples.

[4]Sample WW-18 collected at the owner's request.

[5]Sample WW-30 was collected because this residential well is located in an area not otherwise sampled and is high in nitrate. WW-30 was not evaluated for hormones, pharmaceuticals, isotopic, or age dating as the location was added later in the study.

[6]Co-located samples: LG-02 and LG-03; LG-08 and LG-09; and LG-11 and LG-12.

[7]Samples SP-03 and SP-04 were collected at the same wastewater treatment plant at different times. Sample SP-04 was submitted to EPA's Manchester Laboratory only and was analyzed for a subset of compounds as identified in the table.

SP-04[1]	10154274	WWTP	Liquid	Ammonia (NH3+NH4) as N	35.1	mg/L	MEL	350.1
				Nitrate+Nitrite as N	0.1	mg/L	MEL	353.2
				Total Kjeldahl Nitrogen	57	mg/L	MEL	351.2

Abbreviations

LG - lagoon

MEL - EPA Manchester Environmental Laboratory

SP - wastewater treatment plant influent

WW - water well

WWTP - wastewater treatment plant

Units

mg/L = milligrams per liter

Data Qualifiers

J = The analyte was positively identified. The associated numerical value is an estimate.

R = The data are unusable for all purposes.

U = The analyte was not detected at or above the reported value.

UJ = The analyte was not detected at or above the reported estimated result. The associated numerical value is an estimate of the quantitation limit of the analyte in this sample.

Notes

[1]Samples SP-03 and SP-04 were collected at the same wastewater treatment plant at different times. Sample SP-04 was submitted to EPA's Manchester Laboratory only and was analyzed for a subset of compounds as identified in the table.

Abbreviations

NM = Insufficient Nitrate to complete analysis.
NA = Not analyzed.

Notes

[1]Cascade used Method 300.0 to analyze the samples.

[2]Manchester conducted the nitrate analysis as part of the general water chemistry using Method 353.2.

[3]UNL conducted the nitrate analysis as a part of their isotopic analysis.

See Table C6 notes on page 7 of 7.

Table C6: Phase 3 Analytical Results for Major Ions and Trace Inorganic Elements in Wells, Lagoons, and Wastewater Treatment Plant Influents

Samples were analyzed by the EPA Manchester Environmental Laboratory

Abbreviations

LG - Dairy waste lagoon
SP - wastewater treatment plant influent
WW - water well
WWTP - wastewater treatment plant

Units

ug/L = micrograms per liter
mg/L = milligrams per liter

Data Qualifiers

< = less than

R = The data are unusable for all purposes.

UJ = The analyte was not detected at or above the reported estimated result. The associated numerical value is an estimate of the quantitation limit of the analyte in this sample.

Notes

[1]Samples SP-03 and SP-04 were collected at the same wastewater treatment plant at different times. Sample SP-04 was submitted to EPA's Manchester Laboratory only and was analyzed for a subset of compounds as identified in the table.

Table C7: Phase 3 Analytical Results for Perchlorate in Wells

Samples were analyzed by the EPA Manchester Environmental Laboratory.

Abbreviations

A = Absent

H = Human

MST - Microbial Source Tracking

NA = Not analyzed

ND = Not detected

P = Present

R = Ruminant

TNTC = Too numerous to count

WWTP - Wastewater Treatment Plant

BAC32: This is the screening Bacteroides biomarker. If it is present, further testing is done to determine the specific source. If the test is negative, nothing more is done.

CF128 and CF193: These are two separate biomarkers that identify the presence of ruminant fecal source. Between the two of them, they comprise most of the biomarkers that would be found in ruminants. There may be other biomarkers that could exist in very isolated populations of ruminants, but these two will identify the majority. A "P" would identify detection of the biomarker in the particular sample, an "A" indicates absence of that biomarker in the sample.

HF134 and HF183: These are two separate biomarkers that identify the presence of human fecal source. As above, between the two of these biomarkers, the majority of human source will be detected. Again, a very isolated community might develop a different biomarker. A "P" would identify detection of the biomarker in the particular sample, an "A" indicates absence of that biomarker in the sample.

MST- Microbial Source Tracking. MST contaminants: This identifies by two letter code the kind of fecal source was identified in the particular sample.GB indicates that although Bacteroides DNA was present, the source was neither human nor ruminant. An "A" indicates that no Bacteroides DNA was present in the sample. H indicates human source; R indicates ruminant; H/R indicates that both were found in that sample. To be noted, where there is a species identification, there may be fecal contamination from other species present as well, but due to method limitations is not identified.

Units

#/100ml - number per 100 millilters

<1 - less than one organism

Data Qualifiers

J = The analyte was positively identified. The associated numerical value is an estimate.

Notes

[1]Samples SP-03 and SP-04 were collected at the same wastewater treatment plant at different times. Sample SP-04 was submitted to EPA's Manchester Laboratory only and was analyzed for a subset of compounds as identified in the table.

Table C9: Phase 3 Analytical Results for Pesticides in Wells, Manure Piles, Application Fields, and Crop Soils

Samples analyzed by the EPA Manchester Environmental Laboratory

Abbreviations

SO - soil

WW - water well

NA - Not analyzed

Units

ug/L = micrograms per liter

mg/L = milligrams per liter

Analytical Method

US EPA Method 8270D

Data Qualifiers

< = less than

J = The analyte was positively identified. The associated numerical value is an estimate.

NJ = The analyte was detected at the reported level, the mass spectrum did not meet criteria. The reported value is an estimate.

R = The data are unusable for all purposes.

U = The analyte was not detected at or above the reported value.

UJ = The analyte was not detected at or above the reported estimated result. The associated numerical value is an estimate of the quantitation limit of the analyte in this sample.

See Table C10 notes on page 13 of 13.

Table C10: Phase 3 Analytical Results for Trace Organics in Wells, Lagoons, and Wastewater Treatment Plant Influents

Samples were analyzed by the United States Geological Survey National Water Quality Laboratory.

Abbreviations

WWTP - Wastewater Treatment Plant Influent

NA - Not Analyzed

Units

ug/L = micrograms per liter

Analytical Method

United States Geological Survey (USGS) Standard Operating Procedure (SOP) for the "*Analysis of Waste Water Samples by Gas Chromatography/Mass Spectroscopy"* – USGS SOPs 1433 and 4433.

Data Qualifiers

J = The analyte was positively identified. The associated numerical value is an estimate.

R = The data are unusable for all purposes.

U = The analyte was not detected at or above the reported value.

UJ = The analyte was not detected at or above the reported estimated result. The associated numerical value is an estimate of the quantitation limit of the analyte in this sample.

See Table C11 notes on page 11 of 11.

Table C11: Phase 3 Analytical Results for Wastewater Pharmaceuticals in Wells, Lagoons, Manure Piles, Application Fields, Wastewater Treatment Plant Influents, and Crop Soils

Wastewater pharmaceutical analyses were conducted by the University of Nebraska Water Sciences Laboratory in Lincoln, Nebraska.

Abbreviations

LG - Dairy waste lagoon

NA - Not analyzed

SOP- Standard Operating Procedure

SP - wastewater treatment plant influent

WW - water well

WWTP - wastewater treatment plant

Units

ug/L = micrograms per liter

ug/Kg = micrograms per kilogram

Analytical Methods

Liquids: UNL LC/MS SOP- LCQ-Wastewater-001"*Determination of antibiotics in water and wastewater using off- line solid phase extraction liquid chromatography (LC) - atmospheric pressure electro spray ionization ion trap mass spectrometry (MS) "*.

Solids: UNL SOP-LCQ-Wastesolid-001 "*Determination of antibiotics in solid samples by microwave-assisted solvent extraction (MASE), solid –phase extraction (SPE) and isotope dilution liquid chromatography (LC)- atmospheric pressure electro spray ionization ion trap mass spectrometry (MS)"*.

Data Qualifiers

J = The analyte was positively identified. The associated numerical value is an estimate.

R = The data are unusable for all purposes.

U = The analyte was not detected at or above the reported value.

UJ = The analyte was not detected at or above the reported estimated result. The associated numerical value is an estimate of the quantitation limit of the analyte in this sample.

Table C12: Phase 3 Analytical Results for Veterinary Pharmaceuticals in Wells, Lagoons, Manure Piles, Application Fields, Wastewater Treatment Plant Influents, and Crop Soils

Veterinary pharmaceutical analyses were conducted by the University of Nebraska Water Sciences Laboratory in Lincoln, Nebraska (UNL).

Abbreviations

LG - dairy waste lagoon

NA - not analyzed

SO - solid

SOP- Standard Operating Procedure

SP - wastewater treatment plant influent

WW - water well

WWTP - wastewater treatment plant

Units

ug/L = micrograms per liter

ug/Kg = micrograms per kilogram

Analytical Method

Liquids: UNL SOP "*Analysis of veterinary pharmaceuticals in water samples using a Spark Holland symbiosis on-line C18 cartridge solid phase extraction (SPE) and high pressure liquid chromatography/tandem mass spectrometry (HPLC/MS/MS)"; Document File number: LCMS_VET_PHARM_WATER_001".*

Solids: UNL SOP "*Analysis of Steroids in solid samples (i.e. soils, manure, etc) by microwave-assisted solvent extraction (MASE) and liquid chromatography-tandem mass spectrometry (LC/MS/MS)" (SOP-VetPharmSED-001)"* .

Data Qualifiers

J = The analyte was positively identified. The associated numerical value is an estimate.

R = The data are unusable for all purposes.

U = The analyte was not detected at or above the reported value.

UJ = The analyte was not detected at or above the reported estimated result. The associated numerical value is an estimate of the quantitation limit of the analyte in this sample.

Table C14: Phase 3 Analytical Results for Hormones in Wells, Lagoons, Manure Piles, Application Fields, Wastewater Treatment Plant Influents, and Crop Soils

Samples were analyzed by the U. of Nebraska Water Sciences Laboratory

Abbreviations

LG - dairy waste lagoon

NA - not analyzed

SO - solid

SOP - Standard Operating Procedure

SP - wastewater treatment plant influent

WW - water well

WWTP - wastewater treatment plant

Units

ug/L = micrograms per liter

ug/Kg = micrograms per kilogram

Analytical Methods

Liquids: UNL SOP LCMS-APPI-STEROIDS- WATER-001*"Analysis of steroids in water samples using a Spark Holland symbiosis on-line C18 cartridge solid phase extraction (SPE) and high pressure liquid chromatography/tandem mass spectrometry (HPLC/MS/MS)"* .
Solids: UNL SOP Analyte-Steroids-Solids-001*"Analysis of Steroids in solid samples (i.e. soils, manure, etc) by microwave-assisted solvent extraction (MASE) and liquid chromatography-tandem mass spectrometry (LC/MS/MS)"* .

Data Qualifiers

J = The analyte was positively identified. The associated numerical value is an estimate.

R = The data are unusable for all purposes.

U = The analyte was not detected at or above the reported value.

UJ = The analyte was not detected at or above the reported estimated result. The associated numerical value is an estimate of the quantitation limit of the analyte in this sample.

Table C15: Phase 3 Analytical Results for Isotopic Analyses in Wells, Lagoons, and Wastewater Treatment Plant Influents

Samples were analyzed by the University of Nebraska Water Sciences Laboratory.

Abbreviations

NM = Insufficient Nitrate to complete analysis
NA = Not analyzed
‰ = parts per thousand difference from the atmospheric standard
SMOW = standard mean of ocean water
WWTP - wastewater treatment plant influent

δ15N-NO3 = Nitrogen isotopes of nitrate. Ratio of the nitrogen isotopes 15N and 14N in a specific sample using nitrate compared to a standard of known composition of 15N and 14N. This expressed as the parts per thousand (‰).

δ15N-HN4 = Nitrogen isotopes of ammonia. Ratio of the nitrogen isotopes 15N and 14N in a specific sample using ammonia compared to a standard of known composition of 15N and 14N. This expressed as the parts per thousand (‰).

δ180-NO3 = Oxygen isotopes of nitrate. Ratio of the oxygen isotopes 180 and 160 in a specific sample using nitrate compared to a standard of known composition of 180 and 160. This expressed as the parts per thousand (‰) standard mean of ocean water.

Units

mg/L - milligrams per liter

$$\delta^{15}N\ (‰) = \frac{(^{15}N/^{14}N)_{sample} - (^{15}N/^{14}N)_{standard}}{(^{15}N/^{14}N)_{standard}} * 1000$$

Analytical Methods

UNL SOP: N15 Analysis Dual Inlet IRMS
UNL SOP: Inst-Isoprime EA-18O-001

Samples were analyzed by the United States Geological Survey Chlorofluorocarbon Laboratory.

Analaytical Method

(http://water.usgs.gov/lab/) as well as the research publication *Dating Young Ground Water with Sulfur Hexafluoride: Natural and Anthropogenic Sources of Sulfur Hexafluoride* (E. Busenberg & L. Plummer, 2000).

Data Qualifiers

J = The analyte was positively identified. The associated numerical value is an estimate.

Notes

Over Value: These samples contained more SF6 than can be explained by equilibrium with modern air. Aquifer materials in volcanic areas such as the basalts under the Yakima Valley are known to host naturally-occurring SF6. No anthropogenic source of SF6 is known in the area of the Dairy Cluster.

SF_6 - Sulfur hexaflouride.

The SF6 recharge dating limit is around 1970. Any sample that has a model recharge date before about 1970 is older than the dating range of SF_6. The SF6 method is useful in dating very young waters.

APPENDIX D

DETAILS ON THE ISOTOPIC ANALYTICAL RESULTS

(This page intentionally left blank.)

Appendix D: Details on the Isotopic Analytical Results for the Study

The U.S. Environmental Protection Agency ("EPA") submitted all the water well, dairy lagoon, and wastewater treatment plant (WWTP) influent samples to the University of Nebraska – Lincoln Water Sciences Laboratory ("UNL Laboratory") for isotopic analysis. The results of the isotopic analyses are presented in Table C15 in Appendix C. Summary results for the dairy lagoons are presented below in Table D1. In addition, summary results for water wells are presented in Table D2 below and in Tables 14, 23, 30, and 35 within the main report. Summary results for the WWTP influent are included below as Table D3.

The dual isotopic composition of nitrate (δ^{15}N-NO_3 and δ^{18}O-NO_3) measured in any given water sample is determined by a combination of mixing between different nitrate sources, and in-situ biogeochemical processes. In groundwater, the main biogeochemical process which will significantly alter the isotopic composition of nitrate is denitrification, which requires anoxic conditions. Denitrification will result in a coupled linear increase of both δ^{15}N-NO_3 and δ^{18}O-NO_3 values as the nitrate concentrations exponentially decrease. This combined isotope and concentration pattern was not observed in the water wells, which indicates that the nitrate isotope compositions measured in the water wells are primarily controlled by mixing of one or more nitrate sources. These potential sources are referred to as "end-members" when doing either quantitative or qualitative mixing estimates.

Different end-members tend to have distinct nitrate isotope ranges, either in δ^{15}N-NO_3 or δ^{18}O-NO_3. For example, nitrate derived from fertilizer tends to have much lower δ^{15}N-NO_3 values than nitrate derived from animal waste, but the δ^{18}O-NO_3 values of these two end-members overlap. Nitrate derived from atmospheric sources has much higher δ^{18}O-NO_3 values than all other major nitrate sources due to complex reactions in the atmosphere, but overlapping δ^{15}N-NO_3 values. By measuring both the δ^{15}N-NO_3 and δ^{18}O-NO_3 for all water samples, more information about the possible end-member contributions to any given well can be obtained. If the δ^{15}N-NO_3 and δ^{18}O-NO_3 values of a given water sample fall within the ranges where the isotope values of the potential end-members overlap, then nitrate isotope composition cannot be used to identify the dominant end-member(s).

The isotopic ranges for major nitrate sources are well-established in the literature, however, local end-members specific to a particular study region often have a smaller isotopic range in comparison to world-wide reported values, and therefore measuring the isotopic compositions of local end-members can sometimes help better constrain and interpret nitrate isotope values within a specific data set. In this study, the EPA was able to measure samples representing local animal and human waste end-members.

EPA followed a two-step process to associate a specific source of nitrogen to each water well, dairy lagoon, and WWTP influent sample. First, the concentration of nitrate in each well was compared with nitrate values reported in the literature for unimpacted groundwater. Nitrate concentrations in unimpacted groundwater can be up to 1.1 milligrams per liter (mg/L) (Nolan and Hitt 2003). The second step was to evaluate which of the potential sources or combination of sources (animal waste, synthetic fertilizer, or atmospheric) were likely sources of the nitrate in the water wells. To evaluate whether animal waste was a potential source of the nitrates in the water wells, EPA used the dairy lagoon data presented in Table D1.

Based on the isotopic values observed in this study for nitrogen and oxygen in nitrate and for nitrogen in ammonia, the sources identified include: (1) nitrate formed locally in soil derived from the breakdown of plant material; (2) animal waste; (3) synthetic fertilizers; and (4) accumulation from atmospheric deposition from precipitation and dry deposition. It is important to note that the animal waste category does not differentiate between human and non-human wastes.

Concentrations of nitrate in the two upgradient wells (WW-01 and WW-06), two dairy supply wells (WW-07 and WW-09) and one downgradient well (WW-10) were below 1.1 mg/L (Table C5 in Appendix C). The concentration of nitrate in the majority of downgradient wells was higher. This indicates that animal waste, synthetic fertilizer, atmospheric contributions, or a combination of these sources, are the likely source of the nitrate in the water wells.

Three dairy lagoon samples were collected from each dairy in order to better characterize the local animal waste (includes both human and non-human) end-member. One sample was collected at the influent to each dairy lagoon system (LG-01, LG-04, LG-07, LG-10 and LG-13), and the other lagoon samples were collected at the "discharge" end of the system just before the manure wastes were pumped onto the dairy application fields. Lagoon samples LG-02 and LG-03 were collected from the same lagoon, as were lagoon samples, LG-08 and LG-09, and LG-11 and LG-12. Lagoon samples LG-05 and LG-06 and LG-14 and LG-15 were collected from different lagoons.

The concentration of ammonium was measured in each dairy lagoon sample. The $\delta^{15}N\text{-}NH_4$ values were then quantified for each sample. The $\delta^{15}N\text{-}NH_4$ value is the nitrogen isotopic composition reported for ammonium. It is the ratio of the nitrogen isotopes ^{15}N and ^{14}N in a specific sample compared to a standard of known composition of ^{15}N and ^{14}N. This is expressed as the parts per thousand or parts per mil (‰).

It is expected that the $\delta^{15}N\text{-}NH_4$ values would increase as the waste goes from the lagoon influent to the discharge point. In this process, the lighter ^{14}N isotope volatilizes resulting in a higher proportion of the heavier ^{15}N isotope in the remaining pool of NH_4. These data are summarized in Table D1. The samples collected from the lagoon influent generally have a lower $\delta^{15}N\text{-}NH_4$ ratio than the discharge samples, with the exception of samples LG-10, LG-11and LG-12.

The co-located samples (LG-02 and LG-03; LG-08 and LG-09; and LG-11 and LG-12) all show similar $\delta^{15}N\text{-}NH_4$ values. The average $\delta^{15}N\text{-}NH_4$ value for the five lagoon influent samples (LG-01, LG-04, LG-07, LG-10, and LG-13) is 5.0‰. The average $\delta^{15}N\text{-}NH_4$ value for the 10 dairy lagoons that are located immediately prior to land application (LG-02, LG-03, LG-05, LG-06, LG-08, LG-09, LG-11, LG-12, LG-14, and LG-15) is 8.4‰.

The $\delta^{15}N\text{-}NH_4$ ratios from the dairy lagoon samples provide a better understanding of the local animal waste end-member that could potentially contribute to groundwater nitrate. When NH_4 is converted to NO_3 in oxic groundwater (called "nitrification"), typically there is almost complete conversion of NH_4 to NO_3, and therefore the $\delta^{15}N\text{-}NO_3$ of the newly formed nitrate pool is very similar or equal to the ^{15}N of the NH_4. Therefore, the $\delta^{15}N\text{-}NH_4$ measurements in the lagoons represent minimum ^{15}N end-member values for animal waste derived nitrate, because it is quite likely that there is some additional increase in the $\delta^{15}N\text{-}NH_4$ from the waste ponds (due to continuing NH_3 loss) before it enters the groundwater.

Table D1: Phase 3 – Concentrations of Ammonium, and Isotopic Signatures in Dairy Lagoons

Location	Position in System	Ammonium (mg/L)	$\delta^{15}N\text{-}NH_4$ (‰)
LG-01: Haak	Influent	907	3.4
LG-02:Haak	Discharge	923	10.1
LG-03: Haak	Discharge	896	9.9
LG-04: DeRuyter	Influent	899	6.7
LG-05:DeRuyter	Discharge	1151	10.6
LG-06: DeRuyter	Discharge	1293	10.3
LG-07:D and A	Influent	869	5.4
LG-08: D and A	Discharge	696	10.3
LG-09: D and A	Discharge	658	10.1
LG-10: Cow Palace	Influent	NM	NM
LG-11:Cow Palace	Discharge	274	3.1
LG-12: Cow Palace	Discharge	222	2.0
LG-13:Liberty/Bosma	Influent	469	4.4
LG-14:Liberty/Bosma	Discharge	600	3.3
LG-15:Liberty/Bosma	Discharge	658	13.9

$\delta^{15}N\text{-}NO_3$ ratios measured in water wells that have elevated $\delta^{15}N\text{-}NO_3$ values similar to the $\delta^{15}N\text{-}NH_4$ measured in the waste lagoons would indicate that animal waste is a dominant source of the nitrate in water wells. $\delta^{15}N\text{-}NO_3$ is the nitrogen isotopic composition reported for nitrogen. It is the ratio of the nitrogen isotopes ^{15}N and ^{14}N in a specific sample compared to a standard of known composition of ^{15}N and ^{14}N. This is expressed as the parts per thousand or parts per mil (‰).

Literature values for animal waste indicate a range of $\delta^{15}N\text{-}NO_3$ ratios between 10‰ and 20‰ (Kreitler 1975; Komor and Anderson 1993; and Kendall and Aravena 1999), but with some values lower or higher than this range (Becker and others 2001 and Kendall 1998). For this study, a $\delta^{15}N\text{-}NO_3$ ratio above 8.4‰ was used to indicate that the likely dominant source of the nitrate in the water wells was animal waste (see Table D2 for a summary of the findings for water wells). As discussed above, the average $\delta^{15}N\text{-}NH_4$ ratio at the discharge end of the lagoons was 8.4‰ and this ratio forms the lower end of the expected range for the weights of nitrogen that, after microbial conversion to nitrate, would be transported in groundwater to drinking water wells. The process of isotopic fractionation could be expected to continue after the lagoon liquids escape or are applied as fertilizer. The tendency for the $\delta^{15}N\text{-}NH_4$ value to continue to increase is why 8.4‰ is considered a lower bound for identifying animal waste as a source of nitrate in the water wells. Values of $\delta^{15}N\text{-}NO_3$ below 8.4‰ do not rule out animal waste as a source.

Synthetic fertilizers are another potential source of nitrate in water wells. This study did not directly evaluate the isotopic values for fertilizer used in the study area, but $\delta^{15}N\text{-}NO_3$ ratios for synthetic

fertilizers are often within a range of -4.0 to +4.0‰ (Komor and Anderson 1993; Kendall, C.1998; and Kendall and Aravena 1999). In addition, the lowest $\delta^{15}N\text{-}NH_4$ value from the dairy lagoons was 2.0‰. This result suggests synthetic fertilizers are the likely dominant source of nitrate in water wells when the $\delta^{15}N\text{-}NO_3$ values are below 2.0‰. As with the animal waste, this value does not mean synthetic fertilizer cannot be a likely source of the nitrate in water wells if $\delta^{15}N\text{-}NO_3$ values are above 2.0‰.

For $\delta^{15}N\text{-}NO_3$ values between 2.0‰ and 8.4‰, the source of nitrate in the water wells cannot be confidently attributed to a single source. The source could be animal waste or synthetic fertilizer, or a mixture of the two. In addition, for water wells that suggest an atmospheric contribution, other sources could be solely animal waste, solely synthetic fertilizer, or a mixture of all three with an atmospheric contribution.

Another possible source of nitrate in water wells is atmospheric deposition, although nitrogen contribution from this source is estimated to be less than 2% of the total amount of nitrogen in the Valley (EPA 2012). Because of the very low rainfall in the Lower Yakima Valley, atmospherically deposited nitrate may accumulate in shallow soils in the caliche layer. A caliche layer is a characteristic of desert regions that forms when carbonate minerals accumulate in the shallow subsurface because insufficient rainfall occurs to wash them into the deeper groundwater. Other minerals may accumulate along with the carbonates in areas of very low rainfall. These minerals include gypsum and, if the area is sufficiently dry, nitrates and perchlorate.

As mentioned above, nitrate derived from atmospheric sources has significantly higher $\delta^{18}O\text{-}NO_3$ values in comparison to other major nitrate sources. $\delta^{18}O\text{-}NO_3$ values for pure atmospheric deposition (the atmospheric end-member) typically range from 60‰ to 95‰ (Kendall and others 2007). If the nitrate in any given water sample has a significant component of atmospheric nitrate, then the $\delta^{18}O\text{-}NO_3$ value will be higher than the $\delta^{18}O\text{-}NO_3$ values reported for other sources such as fertilizers and animal waste. Since the major nitrate sources have ranges of $\delta^{18}O\text{-}NO_3$ values, the exact contribution of each end-member cannot be determined, but a qualitative evaluation can be made.

The $\delta^{18}O\text{-}NO_3$ results were used to evaluate the degree to which an atmospheric signature or contribution was dominant in the sample. Ratios above 20.0‰ for $\delta^{18}O\text{-}NO_3$ were considered to have some contribution from atmospherically derived nitrate. This ratio was selected because the literature based on multiple studies of various nitrate sources suggests that $\delta^{18}O\text{-}NO_3$ ratios from synthetic fertilizer, soil cycling, and animal wastes are typically below 15.0‰ (Kendall and others 2007) and the desire to use a value higher than 15.0‰ for $\delta^{18}O\text{-}NO_3$ to ensure that the atmospheric contribution is dominate in the sample. Values of $\delta^{18}O\text{-}NO_3$ below 20.0‰ could have an atmospheric contribution, but it becomes indistinguishable from other sources.

Table D2: Phase 3 – Nitrate Concentrations, Isotopic Signatures, and Interpreted Dominant Source(s) of Nitrate in Wells

Location	Nitrate-N (mg/L)[a]	$\delta^{15}N\text{-}NO_3$ (‰)	$^{18}O\text{-}NO_3$ (‰)	Interpreted Dominant Source
WW-01	0.2	NM	NM	NM
WW-02	3.0	2.7	15	Indeterminate
WW-03	34	2.3	29	Fertilizer and/or animal waste with some atmospheric contribution
WW-04	49.9	3.5	-4.5	Fertilizer and/or animal waste
WW-05	12.8	9.7	7.1	Animal waste
WW-06	0.6	NM	NM	NM
WW-07	1.1	-0.1	NM	Fertilizer
WW-08	11.7	5.3	23	Fertilizer and/or animal waste with some atmospheric contribution
WW-09	NM	NM	NM	NM
WW-10	NM	NM	NM	NM
WW-11	21.6	3.0	18	Fertilizer and/or animal waste
WW-12	43.6	6.2	-1.4	Fertilizer and/or animal waste
WW-13	42	11	16	Animal waste
WW-14	40.7	10	8.5	Animal waste
WW-15	27.4	5.2	30	Fertilizer and/or animal waste with some atmospheric contribution
WW-16	23	5.9	5.8	Fertilizer and/or animal waste
WW-17	23.3	6.9	2.5	Fertilizer and/or animal waste
WW-18	69.6	5.4	44.4	Fertilizer and/or animal waste with Some Atmospheric Contribution
WW-19	36.4	8.7	15.4	Animal waste
WW-20	15	6.3	52.9	Fertilizer and/or animal waste with some atmospheric contribution
WW-21	36.5	7.7	12.2	Fertilizer and/or animal waste
WW-22	16.6	10	11.0	Animal waste
WW-23	17.3	2.2	18	Fertilizer and/or animal waste
WW-24	14	-0.3	12	Fertilizer
WW-25	32.9	2.4	15	Fertilizer and/or animal waste
WW-26	15.1	7.5	6.3	Fertilizer and/or animal waste
WW-27	19.9	8.8	17	Animal waste
WW-28	69.6	5.5	44	Fertilizer and/or animal waste with some atmospheric contribution

[a]The nitrate concentrations are from the UNL isotopic analysis.

Isotopic results were obtained from the ammonium sampled from the inlet to three sewer treatment plants in the Lower Yakima Valley. The plants were located in Zillah, Mabton and Toppenish, and correspond to SP-01 through SP-03. The results for the analysis of $\delta^{15}N\text{-}NH_4$ from the ammonium in the influent are presented below.

Table D3: Phase 3 – Isotopic Signatures, and Nitrogen Enrichment in Wastewater Treatment Plants

Location	$\delta^{15}N\text{-}NH_4$ (‰)	Nitrogen Enrichment
SP-01: Zillah	3.72	Slightly Enriched
SP-02: Mabton	7.43	Ammonia Volatilization has occurred
SP-03: Toppenish	2.70	Slightly Enriched

APPENDIX E

QUALITY ASSURANCE AND QUALITY CONTROL

(This page intentionally left blank.)

Appendix E: Quality Assurance and Quality Control

This project was implemented in three phases. In Phase 1, a geographic information system (GIS) screening application was developed and used to identify potential sample locations and sites in the Lower Yakima Valley for Phase 2 sampling and screening. Phase 1 also developed estimates of the relative nitrogen available for application to the land from different sources. Phase 2 and Phase 3 involved extensive sampling and analysis. A discussion of the quality assurance and quality control (QA/QC) procedures followed in Phase 2 and Phase 3 is presented below.

Phase 2 was implemented following the specifications of the U.S. Environmental Protection Agency (EPA)-approved "*QA Project Plan for Yakima Nitrate Study, Phase 2 – Initial Nitrate/Coliform Screening of Domestic Wells, February 2010"* (EPA 2010a). Deviations from the quality assurance project plan (QAPP) included changes in sample locations and modifications to the analytical method used, sampling method techniques, and additional number of samples collected. The rationale for these deviations was documented in the project team-approved Sample Alteration Form or Corrective Action Form.

In Phase 2 a multi-parameter water quality instrument was used in the field for measuring dissolved oxygen, oxidation/reduction (redox) potential, pH, specific conductance, and temperature. All field instruments were calibrated before use. For quality control, duplicate sample readings and calibration checks were performed. All field testing QC samples met the frequency of analysis, precision, and accuracy checks. The data generated are acceptable and can be used for screening purposes.

In Phase 2, EPA's Manchester Environmental Laboratory ("EPA Manchester Laboratory") received 189 samples for analysis. Of these 189 samples, 102 were analyzed for nitrate and chloride, two were analyzed for nitrate and nitrite, and 123 were analyzed for total Kjeldahl nitrogen (TKN). Two percent of the total nitrate data points were qualified as follows: one sample (10086211) did not meet the holding time requirement and the result was qualified estimated; the nitrate concentration reported for this sample may be biased low. One sample (10086101) exceeded the highest level of the calibration curve and was qualified estimated. Data users are advised to consider the nitrate reported for this sample as biased low. All nitrate data, as reported and qualified, are acceptable for use for all purposes. All of the chloride and TKN analyses met the method required QC criteria. The data as reported are usable for all purposes.

A separate QAPP was developed for Phase 3 sampling (EPA 2010b). Phase 3 samples were collected and shipped to the following laboratories for chemical analysis: EPA's Manchester Laboratory, Cascade Analytical Laboratory, University of Nebraska – Lincoln, Water Sciences Laboratory ("UNL Laboratory"), U.S. Geological Survey National Water Quality Laboratory ("USGS NWQ Laboratory"), USGS Laboratory in Reston ("USGS Reston Laboratory") and EPA's Robert S. Kerr Environmental Research Center in Ada, Oklahoma ("EPA's Ada Laboratory"). The field sampling team and analytical laboratories followed the protocols described in the QAPP with the exception of the deviations identified in Table E1. The quality assurance review summaries for each lab are included below.

Table E1: Deviations from the Phase 3 Quality Assurance Project Plan (QAPP)

Location in QAPP	QAPP Description	Deviation or Action or Modification
Page 11, Table 2, First Column. Surface Soil	"Surficial soil from waste application fields (large area multi-increment sample of at least 30 subsamples…)"	The surface soil sampling method in the QAPP was misidentified as multi-increment sampling. It should have been identified as composite sampling. EPA collected composite surface soil samples comprised of at least 30 subsamples from a depth of 1 inch below the surface.
Page 13, Table 5	Schedule of Tasks	The actual schedule for laboratory analysis, data validation, and report preparation deviated from the schedule in the QAPP.
Page 15, Section 3.1, second full paragraph	"The laboratories performing the sample analysis of drinking water analytes …are SDWA certified and/or accredited."	EPA's Manchester Laboratory and Cascade Analytical Laboratory are Safe Drinking Water Act (SDWA) certified for nitrate analysis in drinking water. EPA's Manchester Laboratory used other standard methods for the analysis of metals and pesticides. The UNL Laboratory, USGS Laboratories and Ada Laboratory are not SDWA certified. A complete list of analytical methods used in Phase 3 is included in Appendix C, Table C-2.
Page 21, Section 4.0, third paragraph	"Water Wells ….Locations are identified as WW01 to WW29"	Water well locations were identified as WW-01 through WW-30 because one additional sample, a field blank (WW-29), was collected.
Page 21, Section 4.0, third paragraph	"Locations are identified as LG01 to LG15 and SP01 to SP03"	An additional wastewater treatment plan influent sample was collected at the Toppenish wastewater treatment plant (SP04) because the laboratory requested additional sample volume.
Page 28, Section 4.2, Shipping Location and Requirements	Samples to be shipped to the UNL Laboratory were to be frozen at -20C.	The on-site freezer trailer could not continuously maintain a temperature of -20C. Samples were transferred to a freezer at WSU. Samples were reported to have arrived frozen at the UNL Laboratory.
Page 33, Section 4.13, second bullet	"Coolers or boxes containing cleaned bottles will be sealed with a custody tape seal during transport to the field or while in storage before use."	After custody seals had been removed from coolers or boxes containing cleaned sample bottles, custody seals were not reapplied if coolers or boxes remained in the custody of EPA at all times.
Page 35, Section 5.0, first paragraph	"The required precision and accuracy for this project is 20% relative percent difference (RPD) …"	For herbicide, pesticide and age dating analyses, the laboratory established duplicate analysis control limits were used instead of the customary 20% RPD.

Location in QAPP	QAPP Description	Deviation or Action or Modification
Page 35, Section 5.0, first full paragraph	"Transfer blanks will be incorporated into the sample schedule at a rate of approximately 5% or once per sample location type."	Transfer blanks were collected for bacterial analysis only.
Page 39, Section 7.2, fourth sentence	"Data validation will be performed by the laboratory for all the analyses prior to the release of data in accordance with each laboratory's quality assurance plan."	The QAPP should have stated "Data **verification** will be performed by the laboratory for all the analyses prior to the release of data in accordance with each laboratory's quality assurance plan." EPA chemists conducted an independent validation of all Phase 3 data.
Page 40, Table 7	Bias of 80-120% was specified for Alkalinity, ammonia, mercury, metals, nitrate+nitrite, TKN and total phosphorus	The laboratory established control limits of 75%-125% were used.
Page 40, Table 7 General Chemistry and Inorganics	Plus 1 duplicate sample for QA out of each 10 drinking water wells. Plus 1 triple sample for QA out of each 20 lagoon samples.	Due to an oversight, no field duplicate or triplicate samples were collected from the water wells or the lagoons.
Page 40, Table 7	Chloride and bromide analysis of lagoon samples.	After analysis at EPA's Manchester Environmental Laboratory, excess volumes of thirteen of the fifteen lagoon samples were shipped to EPA's Laboratory in Ada, OK for analysis of bromide to see if lower detection limits could be achieved. Chloride also was reanalyzed by the Ada Laboratory to determine the Cl:Br ratio for the lagoon samples. The bromide results from the Ada Laboratory also were non-detects, therefore no Cl:Br ratios were determined.
Page 41, Table 8	Varian Plexa SPE cartridge was specified in the sample prep methods column.	The Varian Plexa adsorbent cartridge did not meet the laboratory recovery control limits of 70% to 130% specified in the QAPP. Water samples were extracted using Method 551.1.
Page 41, Table 8	Dichlobenil	Reported as IUPAC 2,6-dichlor-benzonitrile
Page 41, Table 8	Phosmet	Reported as Imidan
Page 41, Table 8	Oryzalin	Reported as Surflan
Page 41, Table 8	N/A	Acid Herbicides were added.
Page 48, Table 12	N/A	Laboratory also analyzed for ^{18}O. No blanks were analyzed for ^{18}O.

Location in QAPP	QAPP Description	Deviation or Action or Modification
Page 50, Table 14	N/A	The USGS laboratory's standard list of trace organic compounds included analytes in addition to those listed in the QAPP. These compounds were analyzed and the data are presented in the report.
Page 58, Table 18	N/A	Table 18 in the QAPP is incomplete. Cascade Analytical Laboratory also analyzed for ammonia solid by Standard Method 4500-NH_3, Nitrate-N/Total Solid by Standard Method 4500-NO_3 E, Ammonium-N by Standard Method 4500-NH_4 H, Nitrate-N/Nitrite by Standard Method 4500-NO_3 F and TKN by 4500N-ORG-C.
Page 58, Table 18	Matrix spike (bias) limits 85-115%.	Matrix spike (bias) limits were 80-120%.

1. EPA's Manchester Environmental Laboratory, Port Orchard, Washington

A Stage 4 data validation was performed by the EPA Region 10 Quality Assurance (QA) team for all the data generated by EPA's Manchester Laboratory (Appendix Table E2).

Table E2: Phase 3 – Chemical Analyses Conducted and Analytical Methods Used by the EPA's Manchester Laboratory

Sample Type	Number of Samples	Parameter or Compound	Analytical Method (Prep)	Analytical Method (Analysis)
Water Wells, Dairy Lagoons, and WWTP Influent	49	TKN	EPA Method 351.2	
	49	NH3	EPA Method 350.1	
	49	Nitrate-Nitrites	EPA Method 353.2	
	49	Total Metals	EPA Method 200.2 (water) SW846 Method 3010A (lagoons)	EPA Method 200.7
	49	Mercury	EPA Method 245.1	
	49	Alkalinity	Standard Method 2320B	
	32	Coliforms	Standard Methods 9221F/9221E/9222B	
	13	Microbial Source Tracking	DNA PCR Techniques	
	49	Bromide, Chloride, Fluoride, and Sulfate	EPA Method 300.0	
	49	Total Phosphorous	EPA Method 365.1	
	30	Pesticides (only water wells)	EPA Method 551.1	SW846 – Method 8270D-SIM
	30	Herbicides (only water wells)	EPA Method 551.1	SW846-Method 8270D-SIM
Soils and Manure	16	Pesticides	SW846- Method 3570	SW846 – Method 8270D-SIM
	16	Herbicides	SW846-Method 8151A	SW846-Method 8270D-SIM

All of the chemical and microbial analyses conducted at EPA's Manchester Laboratory met the project data quality goals and criteria for accuracy, precision, comparability, completion, representativeness, and sensitivity, and are useable for all purposes with the following exceptions:

Nitrate and Nitrogen Compounds

Nitrogen compounds included ammonia, TKN, and nitrate-nitrites. Samples 10154251, 10154252, 10154253, 10154254, 10154255, 10154256, 10154257, 10154258, 10154259, 10164260, 10164261, 10164262, 10164263, 10164264 and 10164265 did not meet the required preservation when they were received at the laboratory. Nitrate/nitrites, TKN, and ammonia results for these samples were qualified estimated with a possible low bias. Thirty-one (31 percent) of the data points (147) were qualified estimated.

Mercury and Alkalinity

Thirty-nine percent (39 percent) of the total mercury data points were qualified estimated based on out of control sample spike and blank spike recoveries. Alkalinity results met all the QC criteria. The mercury and alkalinity data, as reported and qualified, are acceptable for use for all purposes.

Metals

Two dairy lagoon samples, 10164261 and 10164262 (4 percent of the total metals data points), were qualified estimated based on blank contamination. The metals data, as reported and qualified, are acceptable for use for all purposes.

Pesticides and Herbicides

The project data quality goals for precision and accuracy for numerous target analytes were not met for dairy lagoons and WWTPs. As stated above, all of the pesticides and herbicide results for the dairy lagoons and WWTPs could not be quantified and are considered unusable because of (1) the complexity of the sample matrices, (2) holding times that were exceeded, (3) recurring QC failures, and (4) the limitations of modified Method 8270D for detecting pesticides and herbicides at the project reporting levels. However, the pesticides for water and soil, as qualified, are usable for all purposes.

Anions

Anions included chloride, fluoride, bromide, and sulfates. As a result of matrix interferences, the dairy lagoon and WWTP biosolids samples collected were analyzed at 50x dilutions for bromide, fluoride, and sulfate. The reporting limits for these bromide, fluoride, and sulfate were elevated and did not meet the project goals. As qualified and reported, the analytical results for water and soil are acceptable for use for all purposes.

Microbial Source Tracking

Microbial Source Tracking (MST) analysis was performed on nine lagoon and four wastewater treatment plant samples using a polymerase chain reaction (PCR) technique. All quality control measures passed including laboratory QC, sterility controls, and blank analyses. Samples were assessed on a present (P) / absent (A) basis for *Bacteroides* species with possible source identification of general *Bacteroides* (GB), human (H), ruminant (R), or both human and ruminant (H/R).

Bacteria

Twenty-one well water, six lagoon, and three wastewater treatment plant samples were analyzed for total coliform by Standard Method (SM) 9222B, fecal coliform by SM 9221E, and/or *E. coli* by SM 9221F. All quality control measures passed including holding time requirements, laboratory QC, sterility controls, and blank analyses. All lagoon and wastewater treatment samples were qualified estimated ("J") for *E. coli* as the method, SM 9221F, has not been approved for use under the Clean Water Act (CWA).

2. Cascade Analytical Laboratory, Wenatchee, Washington

Nitrate and Other Forms of Nitrogen

Cascade Analytical Laboratory is a certified by the State of Washington to conducted drinking water analysis including analysis for nitrate. It is located in Union Gap and Wenatchee Washington, and analyzed nitrate for this study. Because of the short holding times for certain nitrate analytical methods, Cascade Analytical Laboratory was sub-contracted by Region 10 to analyze the water well, soil, and manure samples for nitrate and nitrogen compounds for Phase 3. A total of 30 water wells, 11 soil, and five manure samples were submitted.

The analytical method used for the determination of nitrate in water samples was Method 300.0. Five samples were analyzed for Total Nitrogen/Solid by AOAC Method 993.13, Ammonia Solid by SM 4500-NH3, and Nitrate-N/Total Solid by SM 4500-NO_3 E. Ten samples were analyzed for Total Nitrogen/Solid by AOAC Method 993.13, Ammonium-N by SM 4500-NH_4 H, and Nitrate-N/Nitrite by SM 4500-NO_3 F. In addition, several samples were analyzed for TKN by 4500-Norg C. A Stage 4 data validation was performed by EPA Region 10 QA team for all data generated by Cascade Analytical Laboratory.

All of the QC samples and sample analysis met the technical acceptance criteria set forth by the methods. The data, as reported, are acceptable for use for all purposes.

Thirty split water samples were collected, shipped to Cascade Analytical Laboratory and EPA's Manchester Laboratory, and analyzed for nitrate using the EPA Method 300.0 (Cascade Analytical Laboratory) and EPA Method 353.2 (EPA's Manchester Laboratory). Both sets of data met all the method-specified QC criteria and are acceptable for use for all purposes. The nitrate concentrations reported by both laboratories are comparable within 10 percent. The following is a list of water samples that were collected, split, and sent to these two labs:10154201 10154202 10154203 10154204

10154206	10154207	10154208	10154211	10154212
10154213	10154214	10154215	10154216	10154217
10154218	10154219	10154220	10154221	10154223
10154224	10154225	10154226	10154227	10154228
10154229	10164209	10164210	10164222	10164230

Bacteria

Cascade Analytical Laboratory analyzed nine well water samples for Escherichia Coli and Total Coliform using a Quanti-Tray method (Standard Method 9223 B). Three of the well water samples along with nine

dairy lagoon samples and one wastewater treatment plant influent sample were analyzed for fecal coliform in accordance with Standard Method 9222 D.

For bacterial analyses, a holding time of 30 hours must be met for drinking water samples and a holding time of 6 hours must be met for wastewater samples. All samples met these requirements, except for the following dairy lagoon and wastewater treatment plant samples: 10154251, 10154252, 10154253, 10154271, 10164263 and 10164264. The fecal coliform results for these samples were qualified estimated based on holding time exceeded. In addition, all sample results that exceeded the upper limit for microbial estimates were reported as "TNTC" or "too numerous to count." The data, as reported and qualified, are acceptable for use for all purposes.

3. EPA National Risk Management Research Laboratory, Robert S. Kerr Environmental Research Center, Ada,

Hormone and Perchlorate Analyses

Fifteen dairy lagoon, three WWTP, and 30 water samples were analyzed for estrogens (17-α-estradiol; 17-β-estradiol;17-α-ethynyl estradiol; estriol; and estrone) by EPA's Ada Laboratory following the in-house standard operating procedure (SOP) "*Quantitation of Estrogens in Groundwater and Animal waste Dairy lagoon Water Using Solid Phase Extraction, Pentafluorobenzyl and Trimethylsilyl Derivatization and Gas Chromatography Negative Ion Chemical Ionization/Mass Spectrometry/Mass Spectrometry, RSKSOP-253, Revision 2, October 2010."*

The same 30 water samples were also analyzed for perchlorate following the modified *USEPA SW846 Method 6850, "Perchlorate in Soils, Water and Wastes Using High performance Liquid Chromatography/Electrospray/Ionization (ESI) Mass Spectroscopy (MS) or Tandem Mass Spectroscopy (MS/MS).* All sample analyses were evaluated following the EPA's Stage 2B Manual Data Validation Process. The summaries of sample and QC analyses were evaluated and laboratory qualifiers were mapped to Region 10 EPA validation qualifiers following the technical acceptance criteria and method quality control specifications. All of the technical acceptance criteria for QC were met by both analyses. Target compounds detected above the method detection limit (MDL) but below reporting limits were qualified estimated, "J." Data detected below the MDL were qualified non-detects, "U," and reported at the MDL level. The data, as qualified, are usable for all purposes.

4. USGS National Water Quality Laboratory, Denver, Colorado

Trace Organics

USGS NWQ Laboratory analyzed fifteen dairy lagoons, three WWTP plant influent, and 30 water samples for trace organic chemicals following the SOP for the "*Analysis of Waste Water Samples by Gas Chromatography/Mass Spectroscopy*" – USGS SOPs 1433 and 4433. All sample analyses were evaluated following EPA's Stage 2B Manual Data Validation Process (S2VM). The summaries of sample and QC analyses were evaluated and laboratory qualifiers were mapped to Region 10 EPA validation qualifiers following the technical acceptance criteria and method quality control specifications.

Data users are advised to consider the values reported as a screen. For full usability, data need further confirmation for the following reasons: (1) data were not thoroughly verified by the validator because of the absence of the instrument raw data output at the time of review, and (2) the laboratory followed their in-house SOP and the recurrence of results out of SOP QC control limits indicates that the data may not be reproducible by a third party. The data reported can only be used for information purposes and a good starting point in determining sample locations for confirmatory analyses.

Samples were analyzed following the technical specifications of the analytical method. Approximately 6 percent of the total data points were qualified unusable based on extremely low surrogate recoveries. Approximately 32 percent of the total data points were qualified estimated due to chromatographic interference and QC results that did not meet the specified criteria.

Trace levels of 4-tert-octylphenol, diethyl phthalate, menthol, p-cresol, tri(2-butoxyethyl)phosphate, tri(2-chloroethyl) phosphate, tri (dichloroisopropyl) phosphate, tributyl phosphate, and triphenyl phosphate were detected in the field blank (WW29). Only the diethyl phthalate in associated sample WW06 detected at a concentration less than 5x the value in the blank was qualified as non-detect, "U," based on blank contamination.

5. University of Nebraska – Lincoln Water Science Laboratory (UNL)

The University of Nebraska – Lincoln Water Science Laboratory (UNL Laboratory) analyzed several different types of compounds. Table E3 provides a summary of the compounds evaluated, number of samples, matrix, and analytical method.
A Stage 2A data validation review was conducted by the EPA QA team on all the data. The validation included the limited evaluation of calibration, QA, and sample analytical summary results. All samples were analyzed following the technical specifications of UNL's in-house SOPs.

General QA Observations for UNL Analyses

UNL data sets may not meet the third-party reproducibility criterion set forth by EPA's Information Quality Guidelines (EPA /260R-02-008 October 2002) for the following reasons: (1) there is no established or standard analytical method for the analysis of the target compounds, and the analytical methods used are for research purposes only, (2) the recurrence of out-of-control QC results; (3)variability in duplicate runs; and (4) compound identification and calculations were not verified at the time of review because the instruments' raw data output was not available.

Twenty-nine water, 15 dairy lagoons, three WWTP, and 16 soil or manure samples were collected and analyzed for wastewater pharmaceuticals, veterinary pharmaceuticals, hormones and steroids, and isotopic nitrogen and isotopic oxygen. The following is a summary of the data validations for UNL:

Table E3: Phase 3 – Chemical Analyses Conducted and Analytical Methods Used by the University of Nebraska – Lincoln Water Science Laboratory

Sample Type	Compound Class	No. of Samples	Analytical Method (Prep)	Analytical Method (Analysis)
Water Wells, Dairy Lagoons, and WWTP Influent	Hormones	47	On-line SPE with C18 clean-up	SOP#LCMS_APPI_ Steroids_Water-001
	Wastewater Pharmaceuticals	47	Off-line SPE-Modified Method 3535	LC/MS SOP-LCQ-Wastewater-001
	Veterinary Pharmaceuticals	47	On-line SPE extraction with citrate buffer	SOP#LC/MS_Vet_P harm_water-002
	Isotopic Nitrogen	47	Analyte Prep 15-002	N15 Analysis Dual Inlet IRMS
	Isotopic Oxygen	47	SOP#Analyte-O18 in Nitrate/$AgNO_3$	SOP# Inst-Isoprime EA-18O-001
	Ammonia	47	Analyte-DISTN15-004	Titrimetric
	Nitrate	47	Analyte Prep 15-002	Titrimetric
Soil and Manure	Hormones	16	Microwave-Assisted solvent extraction (MASE) and SPE	SOP# Analyte-Steroids_Solids-001
	Wastewater Pharmaceuticals	16	Microwave-Assisted solvent extraction (MASE) and SPE	SOP#-Analyte-LCQ-Wastesolid-001
	Veterinary Pharmaceuticals	16	On-line SPE extraction with citrate buffer	SOP#-Analyte-VetPharmSED-001

Wastewater Pharmaceuticals: Samples were analyzed following the technical specifications of UNL's in-house SOP. Data users are advised to consider the values reported as a screen. For full usability, data needs further confirmation for the following reasons: (1) data were not thoroughly verified by the validator because of the absence of the instrument raw data output at the time of review, and (2) there is no established standard analytical method for the analysis of the target compounds and the recurrence of out of control QC results and big variability in the duplicate runs indicated that the data may not be reproducible by a third party. The data reported can only be used for informational purposes only and a good starting point in determining sample locations for confirmatory analyses.

Approximately 10 percent of the wastewater pharmaceutical data points were qualified unusable because of extremely low spike and surrogate recoveries (less than 10 percent). An additional 55% of the total data points were qualified estimated due to out of control recoveries in the associated QC runs. The rest of the data as qualified are usable for all purposes.

Veterinary Pharmaceuticals: No significant problems were encountered with the analysis of soil/solid samples for veterinary pharmaceuticals. Most of the liquid samples (dairy lagoons, well water, and WWTP) underwent multiple analyses because of concentrations of some of the target compounds in the

field blank and also because of matrix interferences. Approximately 9 percent of the total data points were qualified unusable and an additional 18 percent were qualified estimated concentrations with a high bias because of out of control internal standards or calibration. Five lincomycin and three monensin results in the water samples were detected above the reporting limits but were flagged non-detects based on contamination in the associated field blank, WW29. The concentrations reported were calculated using internal standard techniques. Most of the internal standards did not meet minimum area requirements when compared with the daily calibration standards. Therefore, the associated results may be biased high.

Steroids/Hormones: Because of the calibration results, the detected results or reporting limits for androstadienedione, androsterone, progesterone, estrone, α-zearalanol, α-zearalenol, β-zearalanol for samples associated with the calibration run on January 18, 2011, were qualified estimated, "J/UJ." Approximately 15 percent of the total data points were flagged estimated because of calibrations. In addition, some target compounds were qualified non-detects based on contamination in the associated blank.

Isotopic Nitrogen/Isotopic Oxygen Analyses/Ammonium and Nitrate Nitrogen Analyses: Isotopic nitrogen and oxygen were determined using the amounts of ammonium and nitrate-nitrogen in water. No problems were encountered with the isotopic nitrogen, isotopic oxygen, and intermediate ammonia and nitrate nitrogen results. For QC, laboratory reagent blanks, duplicates, and laboratory-fortified blanks were analyzed at the required frequency. All of the results were comparable to each other. Data were not qualified and are usable for all purposes.

6. USGS Laboratory, Reston Virginia

Recharge Age Dating

The USGS Laboratory located in Reston, Virginia (USGS Reston Laboratory) analyzed the recharge age of the water well samples following the SF_6 procedure.

Limitations of the Method: The recharge dating procedure is a statistical calculation derived from the SF_6 gas evolved in the sample and other existing data. It is applicable to young groundwater systems aged 1970 to present. This procedure is not applicable to areas with high anthropogenic and natural SF_6 background values such as indicated by samples WW-01, WW-11, WW-12, WW-13, WW-23, and WW-28. As a result, age could not be measured in those samples because of the high values of SF_6 as dissolved gases. These samples may indicate areas where localized anthropogenic sources of SF_6 exist. Alternatively, volcanic rocks can contain more SF_6 than the average atmospheric concentrations of SF_6 and the volcanic terrain and mineralogy of the sediments in the local aquifer may be the source of the SF_6.

The USGS Reston Laboratory flagged these six water wells samples with a "C" qualifier, meaning contaminated. For clarity, the validator replaced the "C" qualifier with "NM," not measured. In addition, there were also some samples with recharge calculated dates before 1970. The dating technique used provides only a range, and data users should be warned that the reported recharge ages are estimates.

APPENDIX F

DAIRIES AND NITROGEN

(This page intentionally left blank.)

Appendix F - Dairies and Nitrogen

Animal feeding operations (AFOs) such as dairies generate large volumes of waste of the following types: animal manure and urine, hair and corpses, bedding and spilled feed, wash-flush water, and other processing wastes. If properly stored and used, manure from animal feeding operations can be an environmentally sound approach to fertilizing fields. However, if not managed correctly, the waste produced by AFOs can pollute the environment, including groundwater (NRCS 2008 and EPA 2004).

Animal wastes applied to the land can contaminate groundwater and surface water. This problem has received increasing attention as livestock operations have become more concentrated, with a trend toward more animals on fewer farms and less land (EPA 2001). In 1998, there were 71 dairies in Yakima County that generated 20,162,500 pounds of waste nitrogen. In 2010, the number of dairies contracted to 67 but the amount of nitrogen they generated increased by more than 50 percent to 33,278,300 pounds (WSDA 2010). Over this time period the amount of waste generated by the average Yakima Valley dairy increased substantially.

Concentrated animal feeding operations produce large amounts of waste in small areas (EPA 2004). Rapid growth in the amount of nitrogen per dairy poses waste disposal challenges. It can become increasingly difficult to effectively store and manage the waste onsite, and to find enough land on which it can be safely applied without causing pollution of groundwater and surface water.

A dairy cow produces considerable amounts of nitrogenous organic waste, typically in the range of 110 to 120 pounds of manure per day (EPA 2009). A lactating dairy cow excretes about 328 to 405 pounds of nitrogen over the same time period (USDA 2009). In a typical dairy, liquid waste from the cow pens is flushed with water into a ditch and then may go to a solids separator, which removes most of the solids. Then the liquid waste may drain into a lagoon, or into a sequence of lagoons. This allows time for additional solids to settle out to the bottom of the lagoon(s). Periodically, dairy lagoons fill with solids and must be dredged. After the liquid has passed through the lagoon system it is typically applied with irrigation water to wastewater application fields. Solids, either from the cow pens, aprons, the solids separator, or from the dredged lagoons, are also usually distributed onto the application fields as fertilizer for crops.

Agricultural ditches or creeks can receive nitrogen from overland runoff, discharges from agricultural return flows, or discharges from application fields. These surface waters can infiltrate into the underlying soils and carry nitrogen down to the aquifer. Contaminated surface water in creeks and ditches can carry nitrogen away from the dairy footprint and transport it into the soil column and groundwater at off-site locations.

As they age, underground pipes transporting dairy waste can deteriorate and develop cracks and holes resulting in leakage of liquid over time. Pipes can crack when the soils around them settle or shift, and they can be damaged by heavy equipment. Typically, it is difficult to determine if underground pipes are leaking once they have been installed unless a leak detection system was incorporated into the design or other integrity testing, such as pressure testing, is performed.

Intact concrete slabs are relatively impermeable, but liquid can move through cracks that occur from ground settlement, through unsealed joints between slabs, or from animal waste spillage off the slab onto the ground.

The rate of leakage, or seepage, from manure lagoons can be significantly reduced by the presence of an engineered liner. However, several studies have concluded that clay liners do not completely prevent leakage. A study in southwest Kansas reported seepage rates from swine and cattle waste lagoons lined with compacted soil liners ranging from 0.2 to 2.4 millimeters per day based on measurements of evaporation and changes in water depth in response to the addition or removal of waste (Ham 2002). Harter and others (2002) inferred manure lagoon leaching rates on the order of 2 millimeters per day at a site in California's Central Valley. Leakage from manure lagoons with clay liners has also been reported by Ritter and Chirnside (1987) and by McCurdy and McSweeney (1993).

Studies have shown that manure solids do not completely "self-seal" unlined lagoons. For example, when researchers analyzed samples from the vadose zone (the unsaturated zone above the water table) downgradient of unlined waste lagoons at five Texas dairies, they found that three of the five sites exhibited nitrate levels in excess of the maximum contaminant level (MCL) (Frarey and others 1994).[29] The term "sealing," as it is sometimes used with regard to dairy lagoon solids, is misleading because it suggests complete containment of the wastewater. The term refers to only a reduction in the seepage rate. Ham and DeSutter found that in new lagoons constructed without clay liners, permeability decreased on average by a factor of five after addition of waste to the lagoons, indicating some permeability reduction over time from organic sludge buildup.

Irrigation with manure lagoon water is a common animal waste disposal practice as it can be used as fertilizer while reducing the volume of liquid waste stored in the lagoons. Nitrogen is an essential nutrient for plant growth. However, if too much nitrogen or water is applied to a field, nitrogen can migrate downward and contaminate groundwater. The potential for nitrogen migration is increased if surface soils are highly permeable.

Nutrient Management in Washington

Because dairies generate large quantities of animal waste that can pollute surface water and groundwater, the State of Washington requires all newly licensed Grade A milk[30] producers to have an approved Nutrient Management Plan (NMP) on site within 6 months of licensing, and a certified NMP on site within two years of licensing. "Approved" means the local conservation district has determined that the facility's plan to manage nutrients meets all the elements identified on a checklist established by the Washington Conservation Commission. Certified means the local conservation district has determined all plan elements are in place and implemented as described in the plan. To be certified, both the dairy operator and an authorized representative of the local conservation district must sign the plan.

The checklist contains 20 elements that the dairy must meet in order to receive a license. Most dairies keep their NMPs and associated sampling data on location and they are not available for public review. At the end of the growing season, operators are required to collect soil samples from their fields to which they apply manure or dairy waste water and test for nitrogen. Soil nitrogen concentrations are not to

[29] Environmental Impacts of Animal Feeding Operations, U.S. Environmental Protection Agency, Office of Water Standards and Applied Sciences Division, December 31, 1998. Page 14.

[30] In the United States, Grade A milk refers to milk that is produced under sufficiently sanitary conditions to qualify for fluid (beverage) consumption.

exceed 45 parts per million (ppm) at the end of the growing season. Adherence to this guideline reduces, but does not eliminate the potential for nitrogen to move below the plant root zone and potentially contaminate groundwater.

Consequences of Waste Mismanagement

Improperly stored or used, animal waste can pollute rivers and groundwater, including underground drinking water supplies. Inadequately sized, unlined, or poorly lined lagoons or other storage structures allow manure to escape into the surrounding environment. Poorly maintained and unlined corrals can allow contaminated wastewater to seep into groundwater. Many AFOs also lack necessary stormwater runoff controls that divert rainwater and snowmelt from the animal confinement area. Stored manure can be washed into nearby streams or infiltrate into the soil column. Applying too much AFO wastewater to fields too quickly or by inadequate methods can also cause the pollutants in animal waste to pollute streams or groundwater before they can be completely absorbed by the land and crops. In some cases, an AFO's location - for example, on hillsides, along streams, and atop sensitive groundwater areas - complicates sound animal waste management practices. Animal waste has the potential to contribute contaminants such as nutrients (nitrogen or phosphorus), organic matter, sediments, pathogens (*E. coli*, giardia, or cryptosporidium), heavy metals, hormones, and antibiotics to groundwater and surface water (EPA 2011 and EPA 1999).

Nitrate Transport

Water wells can facilitate the downward migration of nitrogen. Water can flow downward outside a well casing. If a casing is cracked or deteriorated, water can migrate down the well shaft. Negative pressure created by the well pump can pull water from more shallow, contaminated parts of the aquifer downward more quickly that it would otherwise migrate. Improperly abandoned wells (that were not sealed to prevent the downward migration of shallow groundwater) can serve as conduits for downward water migration. A comparison of historical aerial photographs shows that a number of houses that used to exist on Dairy Cluster property have been demolished or removed. Some of these houses were situated where dairy animal waste application fields now exist. EPA has asked the dairies for documentation that any wells abandoned on their property were properly sealed on closure to prevent contaminant migration, but they have declined to provide this information.

Relatively high-production dairy supply wells are often located on the facility they serve, in areas where the shallow aquifer could become contaminated with nitrate from dairy operations. Dairy supply wells may be screened in the upper basalt layers below the shallow, alluvial aquifer. If the well casings are placed down to the top of the first basalt layer but not sealed to it, contaminated water from the shallow aquifer may migrate down the outside of the well casing into the water-bearing zones between the upper basalt layers. During the cooling process following a volcanic eruption, basaltic flows, like those in the Yakima Valley, develop significant fracture permeability. These fractures can serve as preferential pathways for the migration of contaminated groundwater. Dairy production wells and irrigation wells are generally high production wells with large pumps.

APPENDIX G
IRRIGATED CROPS IN THE YAKIMA COUNTY

(This page intentionally left blank.)

Appendix G: Irrigated Crops in the Yakima County

The Yakima County is one of the world's most fertile growing regions with more than 240,000 acres of cropland in the county (USDA 2007a). Agriculture is the largest economic sector in Yakima County and it accounts for approximately 70% to 80% of land use. The top seven crops account for about 90% of the agricultural acreage in Yakima County (USDA 2007b):

- Orchards (about 95,000 acres)
- Corn for silage and grain (about 42,000 acres)
- Alfalfa hay (about 37,000 acres)
- Hops (about 19,000 acres)
- Mint (about 12,000 acres)
- Winter wheat (about 9,000 acres)
- Haylage (about 8,000 acres)

Nitrogen is essential to crop growth and development. This nutrient can be supplied in the form of fertilizer as synthetic compounds or through organic-based amendments including manure, plant residues, and for legume plants like alfalfa, by atmospheric nitrogen-fixing Rhizobium bacteria. Nitrate is the principal form of nitrogen used by plants, and numerous biological and chemical processes result in the conversion of nitrogen-containing compounds to nitrate.

The amount, timing, frequency, and form of nitrogen fertilizer affect the amount of nitrogen (in the form of nitrate) available for uptake. Many synthetic nitrogen fertilizers are readily available for assimilation into the plant. Organic forms of nitrogen fertilizer, such as manure or crop residue, require degradation and transformation over time and release nitrate at a slower rate than synthetic fertilizers. Other factors such as denitrification in the soil by microorganisms, soil type, and volatilization to the atmosphere, also affect the amount of nitrogen available for plant uptake. Regardless of the form of nitrogen, application of nutrients or water at rates greater than plant demand can result in excess nitrate infiltrating through the soil below the root zone into the groundwater.

Nitrogen Application to Irrigated Crops

It is likely that both historic and current use of nitrogen-based fertilizers and irrigation methods in Yakima County contribute to groundwater nitrate levels (Ecology 2010). Crop management has advanced substantially over the past 20 years with more precise nutrient and water management for many crops grown in the Yakima County including hops, grapes, and tree fruit. Based on recommended rates, EPA estimated the amount of nitrogen that is being applied to irrigated crop fields (EPA 2012) by determining the amount of irrigated crop acreage for individual crops (USDA 2007a) and multiplying that by the WSU fertilizer application guidelines (WSU 2009). When the 2007 census did not provide adequate information, crop data from the 2002 Census of Agriculture was used (USDA 2002).

Nitrogen application rates may be based on yield goals, soil type, and existing residual nitrate levels as determined by soil or plant tissue tests. The development of recommended agronomic nitrogen application rates does not take into account protection of groundwater. Since published application rates specific to Yakima County could not be found, the recommended average nitrogen application rates for

each crop was obtained from the Washington State University fertilizer guidelines (WSU 2009). For each type of crop, WSU recommends a range of nitrogen application bounded by a high and low application rate. The annual nitrogen application rate for each crop was estimated by averaging the high and low rates. These are estimated rates and actual application rates by farmers vary.

Below is a list of the crops that EPA estimates have potentially the highest nitrogen demand for fertilizers, either synthetic, organic, or both based on the WSDA crop data (WSDA 2008) and WSU fertilizer guidelines (WSU 2009):

- Corn for silage and grain – 32%
- Orchard Land – 21%
- Hops – 9%
- Mint for oil, both peppermint & spearmint – 8%
- Alfalfa Hay – 7%
- Winter wheat for grain – 6%

These six crops account for nearly 83% of the total potential nitrogen loading from crop fertilization in Yakima County. Corn, when either grown for silage or grain, accounts for the greatest potential nitrogen loading due to its high nitrogen demand and high biomass yield potential. Silage corn is now a common crop associated with dairy operations in Yakima County. Washington State University Fertilizer Guides estimate total nitrogen requirements for a 30 ton yield of corn silage to be approximately 220 pounds per acre per year.

Orchard land has a relatively low recommended nitrogen application rate of approximately 50 pounds per acre per year, but because the total acreage of orchard land is large it accounts for high nitrogen loading in Yakima County for irrigated crops. The crop management practices for orchard land are generally closely monitored because of the need to ensure a high quality product for consumers (Peck and others 2006).

The form of fertilizer applied may also be constrained by crop physiology. Application of manure solids on mint and alfalfa is limited as these perennial crops cannot withstand tillage or incorporation of manure but could accept a liquid form of dairy waste (Mitchell and others, 1992). Application of manure to hop fields may be limited to amendment of soil prior to planting because hop production trellises limit manure incorporation between rows. Food safety concerns for directly consumed crops, such as apples, limit the application window for manure. The National Organic Program, Washington State Organic Standard, and USDA Good Agricultural Practices (GAP) prohibit the application of raw manure on any directly consumed crop 90 days prior to harvest and require incorporation of the waste into the soil (WSDA 2009).

Irrigation Practices

In addition to fertilizer, irrigation is a significant component of the Yakima County crop production. Water quality violations of total suspended sediment in the Yakima River led to enactment of Total Maximum Daily Load (TMDL) limits in the late 1990s. Since then, significant progress has been made in reducing soil erosion from agricultural fields through cost share incentive programs for growers to convert from highly erodible irrigation systems (rill and flood) to less erosive sprinkler-based or drip

irrigation systems (NACD 2008). However, nitrate leaching may occur under any irrigation system, including sprinkler based, if irrigation water is applied beyond crop plant water demand.

Estimates of predominant irrigation methods for the top seven crops in Yakima County, based on acreage, are shown in Figure G1 (WSDA 2008). The irrigation method was estimated by quarter section and resulted in combinations of irrigation system types as shown by the example center pivot/rill. Rill irrigation is the practice of applying water to row crops via small ditches or channels between the rows made by tillage implements. Apples on sprinkler had the greatest acreage at 27,388 acres, followed closely by corn on rill irrigation at 22,145 acres.

Detailed irrigation water management studies conducted by universities, industry and agencies in the past have documented that rill (surface) irrigation results in significantly more deep percolation of irrigation water than sprinkler irrigation (USDA 1997). Drip irrigation has the lowest deep percolation rate. Figure G1 shows that there are approximately 22,145 acres of rill or surface irrigated cropland in Yakima County and of that, corn and wheat which are both annually seeded crops make up 38% of the total irrigated acres.

No published data are available for irrigation scheduling or management for Yakima County crops. USDA National Agriculture Statistics Service (NASS) conducted a survey in 2007 on the methods used by crop producers on when to irrigate (USDA 2007b). For Washington State, nearly 70% of irrigated farms surveyed use qualitative factors to determine water demand such as calendar scheduling, delivery by the irrigation provider, or crop appearance. It was estimated that less than 30% of Washington irrigated farms use quantitative methods such as crop evapotranspiration (ET), crop models, or soil or plant sensors to determine irrigation water quantity and application timing.

AUTHORS & ACKNOWLEDGMENTS

This report was produced by the Center for Agriculture and Food Systems at Vermont Law and Graduate School. The author of this report is **Ruthie Lazenby** (she/her), LLM Fellow and Staff Attorney at the Environmental Justice Clinic at Vermont Law and Graduate School.

This report was made possible with support from the National Agricultural Library, Agricultural Research Service, US Department of Agriculture. The report benefited from significant writing, input, and editing support from several members of the Center for Agriculture and Food Systems at Vermont Law and Graduate School, including **Laurie J. Beyranevand**, Director and Professor of Law; **Lihlani Nelson**, Associate Director and Research Fellow; **Claire Child**, Assistant Director and Research Fellow; **Whitney Shields**, Project Manager; and **Molly McDonough**, Environmental Communications Specialist.

About the Center for Agriculture and Food Systems

Vermont Law and Graduate School's Center for Agriculture and Food Systems (CAFS) uses law and policy to build a more sustainable and just food system. In partnership with local, regional, national, and international partners, CAFS addresses food system challenges related to food justice, food security, farmland access, animal welfare, worker protections, the environment, and public health, among others. CAFS works closely with its partners to provide legal services that respond to their needs and develop resources that empower the communities they serve. Through CAFS' Food and Agriculture Clinic and Research Assistant program, students work directly on projects alongside partners nationwide, engaging in innovative work that spans the food system. Please visit www.vermontlaw.edu/cafs to learn more.

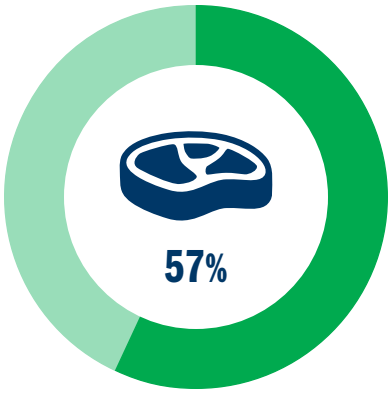
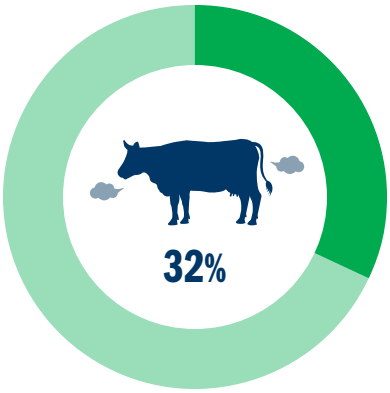
INTRODUCTION



THE WORLD IS ON TRACK TO EXCEED A 2° C INCREASE DURING THE 21ST CENTURY, an outcome scientists have described as catastrophic.[1] Direct impacts on the food and agriculture sectors will be far-reaching.[2] Already, climate-related impacts to farming include "observed changes in extremes such as heatwaves, heavy precipitation, droughts, and tropical cyclones."[3] These changes impact both crop and livestock production. Experts predict that further warming will continue to dramatically affect the "global water cycle and its variability, global monsoon precipitation and the severity of wet and dry events."[4]

In regions like eastern North Carolina, home to the United States' top two pork producing counties,[5] producers will experience more regular hurricanes of greater magnitude.[6] California's Central Valley, which provides cropland for over 250 different crops[7] and houses 80 percent of the state's milk cows,[8] already relies on the second most over-pumped aquifer in the nation while facing substantially drier conditions as a result of climate change.[9] These impacts will disproportionately harm vulnerable populations[10] in addition to historically marginalized farmers, who will be the first to lose their livelihoods.[11] Climate change will force agriculture to adapt—either now, through innovation to mitigate increased warming, or later, as regional climates become incompatible with existing models of food production.[12]



It is clear that the food and agriculture sector will bear significant impacts from climate change, but this sector is also a major contributor of greenhouse gas (GHG) emissions. Animal agriculture, in particular, is responsible for approximately 20 percent of global GHG emissions and 57 percent of food related emissions.[13] Animal agriculture's primary contributions to climate change result from methane and nitrous oxide emissions. Methane has a global warming potential 28 to 36 times that of carbon dioxide on a 100-year timescale and nitrous oxide has a global warming potential 265 to 298 times that that of carbon dioxide on a 100-year timescale.[14] Moreover, while emissions from the energy sector have decreased as a result of emission reduction policies, GHG emissions from agriculture have increased over recent decades with this trend projected to continue.[15] Consequently, addressing emissions from agriculture is increasingly critical.

One approach to reducing atmospheric GHGs from livestock involves capturing emissions from manure through the use of anaerobic digesters.[16] Proponents of this approach herald it as a win-win. Manure biogas systems reduce GHG emissions by capturing GHGs that would otherwise be emitted and can displace the use of fossil fuels. Additionally, this new fuel source (biogas) creates a new revenue stream from a former waste product. In a 2017 press release announcing federal funding to help farmers construct biogas systems, the United States Department of Agriculture (USDA) articulated the conventional wisdom of the emissions reduction claim, stating:

> "Anaerobic digesters actually provide two-fold greenhouse gas reduction. First, they capture methane that otherwise would be emitted from the manure into the atmosphere. . . . Second, by utilizing the trapped biogas as a renewable energy source, digesters displace the need for additional fossil fuels."[17]
>
> **– LAURA MELLING**

While these claims sound promising, they omit important nuance. **Animal agriculture generates emissions throughout the operation—from land conversion to enteric fermentation (the emissions generated from ruminant burps), to transportation.** It is imperative that policymakers and others recognize that manure biogas systems reduce emissions from only one part of this system—manure management. At the same time, manure biogas systems rely on the ongoing production of large quantities of livestock manure—the source of manure management emissions—to function. Espousing these systems to the exclusion of other emissions mitigation measures can foreclose the potential to make important modifications throughout the livestock life cycle. Ultimately, this reinforces current conventional models of livestock production at the expense of farmers using more sustainable production models.

Currently, policymakers are dedicating increasing amounts of public funding and attention to manure biogas as compared to other policy interventions that can reduce livestock emissions. Recently, the American Biogas Council suggested that the US could support at least another 13,740 potential new biogas systems, including 8,300 on farms, in addition to 4,000

What is Methane?

"Methane is produced as part of normal digestive processes in animals. During digestion, microbes resident in an animal's digestive system ferment food consumed by the animal. This microbial fermentation process, referred to as enteric fermentation, produces CH4 as a byproduct, which can be exhaled or eructated by the animal. The amount of CH4 produced and emitted by an individual animal depends primarily upon the animal's digestive system, and the amount and type of feed it consumes."

Source: Inventory of US Greenhouse Gas Emissions and Sinks (1990-2020), Environmental Protection Agency

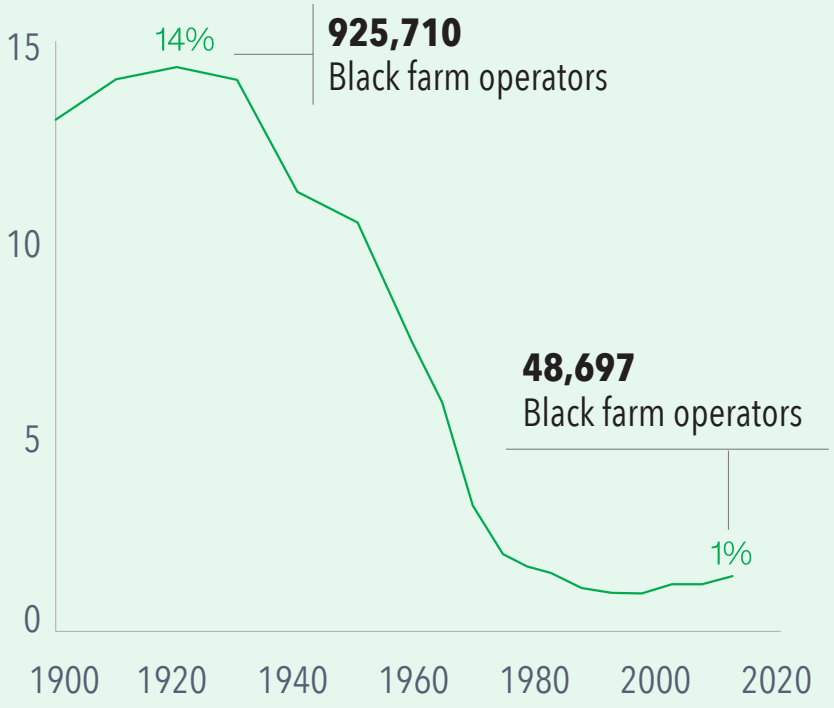
What is Enteric Fermentation?

"Enteric fermentation is fermentation that takes place in the digestive systems of animals. In particular, ruminant animals (cattle, buffalo, sheep, goats, and camels) have a large "fore-stomach," or rumen, within which microbial fermentation breaks down food into soluble products that can be utilized by the animal."

Source: AP-42: Compilation of Air Emissions Factors, Environmental Protection Agency

What are Biosolids?

"Biosolids are a product of the wastewater treatment process. During wastewater treatment the liquids are separated from the solids. Those solids are then treated physically and chemically to produce a semisolid, nutrient-rich product known as biosolids. The terms 'biosolids' and 'sewage sludge' are often used interchangeably."

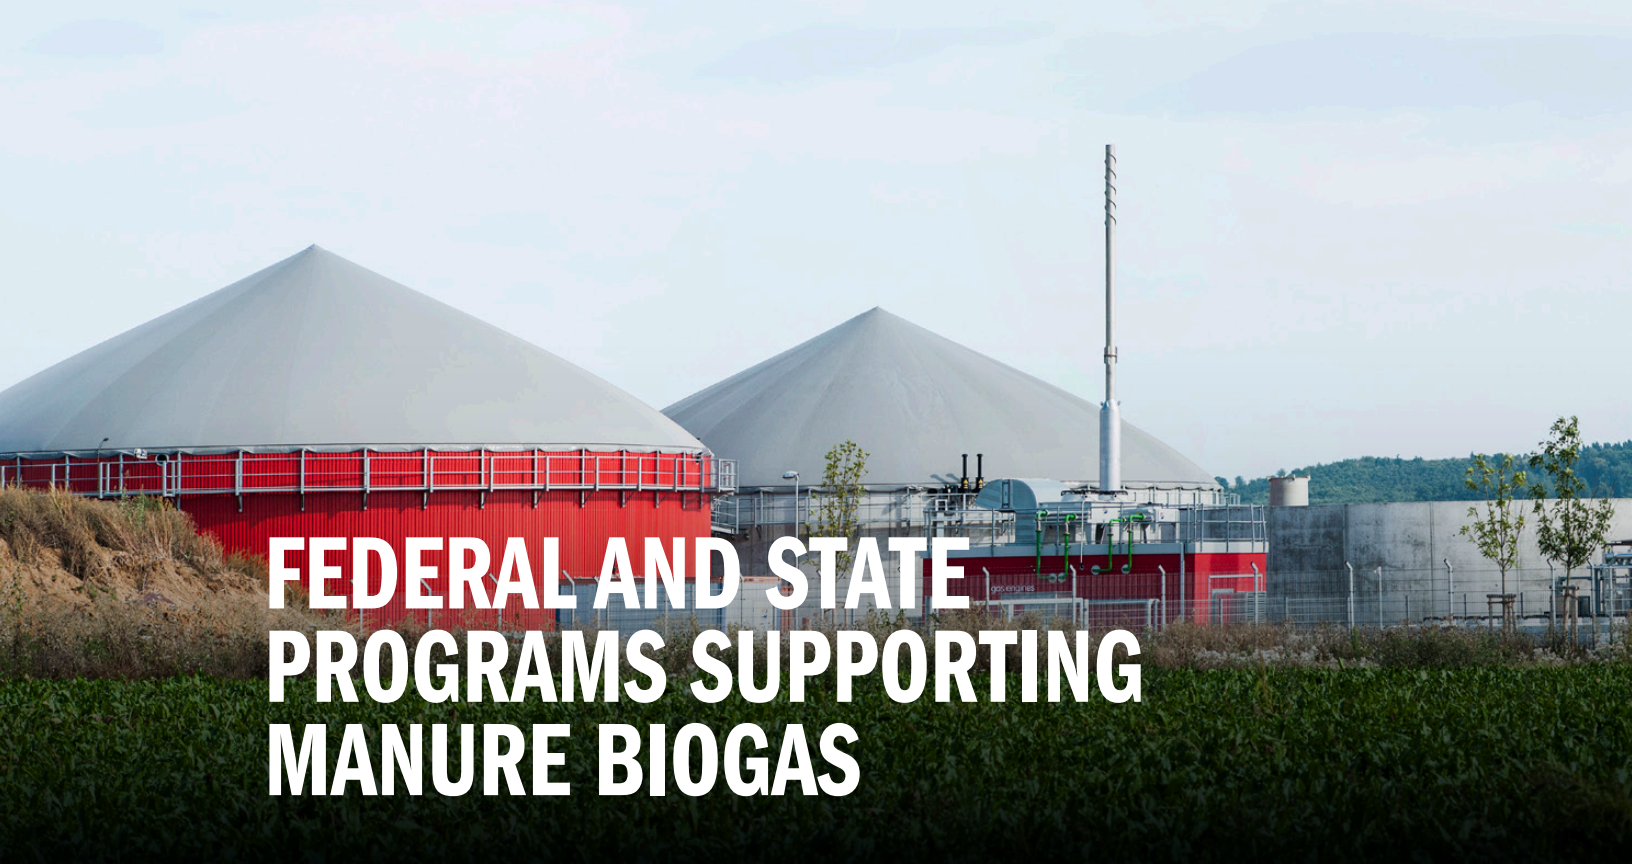


Source: Environmental Protection Agency

for wastewater, 1,000 for food scraps, and 440 for landfills.[18] Biogas systems are expensive to construct and operate. They require substantial investment into long-lasting, durable infrastructure such as pipeline interconnections and facilities upgrades. As more public and private resources are dedicated to this infrastructure, the incentives to continuing using these systems will increase.

To date, many discussions on the benefits of manure biogas fail to account for the concerning and negative implications associated with widespread adoption of manure biogas systems. For example, the climate implications resulting from the need for these systems to engage in long-term production of massive quantities of livestock manure (or other biosolids) to recoup the fixed upfront costs of installation and continued revenue generation is rarely addressed. To illustrate this point, the public programs subsidizing production and sale of biomethane from these operations provide incentives for the ongoing production of the core input—livestock manure—even as climate scientists warn that greater reductions from animal agriculture are necessary.[19] Promoting widespread investment in and adoption of manure biogas systems will inevitably impact livestock agriculture for years, if not decades, into the future, creating potential barriers for more substantial and systemic climate mitigation measures for the sector.

Moreover, because manure digesters are typically feasible only for industrial-scale livestock operations, the largest confined animal feeding operations will reap the financial and public relations benefits that accompany the installation of digesters. This is not a new trend: today and historically, large-scale commercial operations have benefited from the lion's share of federal funding for agriculture. Due to decades of discriminatory lending by USDA,[20] the majority of these operations are owned by white farmers.[21] Racism and discriminatory lending by the federal government over the past century has resulted in a dramatic loss of Black-owned land and farms across the board (one recent analysis calculated this dispossession to total $326 billion).[22] This disparity is even more pronounced for larger agricultural operations.[23] However, in some parts of the country, the substantial environmental impacts generated by these larger agricultural operations disproportionately harm Black, Indigenous, and communities of color.[24]



The share of Black farmers has declined significantly over the last century. Today just 1.4 percent of farmers identify as Black.

Source: Black farmers in the US: The opportunity for addressing racial disparities in farming, McKinsey & Company

Anaerobic digesters, in contrast to alternative mitigation measures, are an appealing means to reduce livestock emissions in industrial animal agriculture because they require no change to the structure of conventional livestock operations and manure management. On the contrary, these systems function by ensuring the continuity of both the existing system and its beneficiaries. This fails to consider and plan for the systemic changes needed in conventional operations and manure management due to the current, near, and long-term impacts of climate change.[25] Consequently, policymakers should immediately begin to proactively plan for the future by assessing the full range of suitable mitigation measures and supporting those that will provide for long-term sustainability and climate mitigation. As part of this process, policymakers must also critically evaluate the environmental justice impacts to neighboring communities and equity implications of elevating biogas systems over other mitigation measures.

This report analyzes and evaluates the extensive adoption and support of manure anaerobic digesters with a specific focus on the resulting equity implications, a goal explicitly aligned with two executive orders issued by the Biden Administration—Executive Order 14008: Tackling the Climate Crisis at Home and Abroad[26] and Executive Order 13985: Advancing Racial Equity and Support for Underserved Communities Through the Federal Government.[27] The report begins by surveying existing funding opportunities for manure biogas systems and the fuels they produce. It then addresses the direct environmental impacts of installing and operating these systems, including a brief discussion about the methodology used to account for life cycle emissions. The next section evaluates alternative methods to reduce livestock emissions, indirect environmental impacts of adopting manure biogas as the primary means to reduce GHG emissions from livestock operations, and the equity impacts. The report concludes with a set of recommendations for policymakers and regulators as they consider the role this technology should play in shifting livestock agriculture toward a more equitable, just, and climate-smart model.

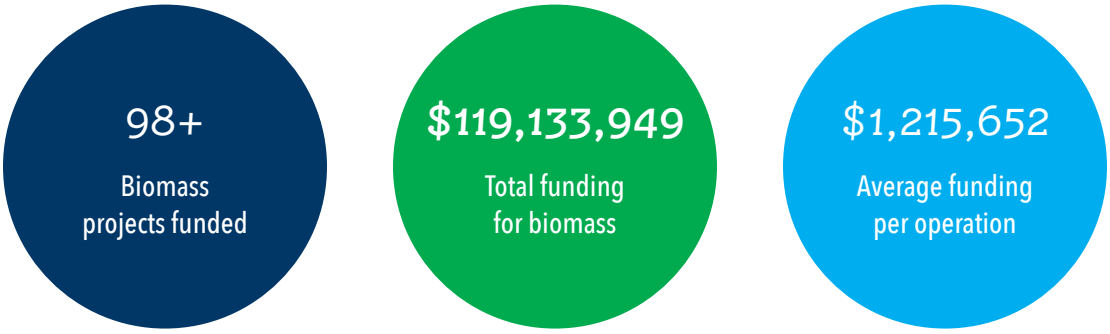
FEDERAL AND STATE PROGRAMS SUPPORTING MANURE BIOGAS

THE BIDEN ADMINISTRATION HAS CONSISTENTLY EMPHASIZED ITS COMMITMENT TO CLIMATE-SMART AGRICULTURE and tasked a number of federal agencies with collecting input from stakeholders and developing plans to address the climate crisis.[28] USDA was directed to submit a report to the administration laying out an "agricultural and forestry strategy."[29] In USDA's 90-Day Progress Report on Climate-Smart Agriculture and Forestry,[30] the agency embraced the president's "focus on developing a climate-smart agriculture and forestry strategy that employs proven conservation practices," announced plans to reduce methane from livestock,[31] and significantly funded research efforts targeted at these reductions.[32] With this new momentum, policy attention and interest in manure biogas has never been greater due to the perception that it provides an easy solution to reduce atmospheric emissions without requiring significant changes to the conventional industrial livestock model. This section surveys many of the existing and overlapping funding sources and incentive programs for manure biogas.

Grants & Loans Covering Start-Up Costs

Direct financial support for anaerobic digester systems is available to livestock facilities in the form of grants and loans. At the federal level, the Rural Energy for America Program (REAP) provides guaranteed loan financing and grant funding for the construction of biogas systems.[33] Federal funds for biogas systems can also be obtained through USDA's conservation programs—the Environmental Quality Incentives Program (EQIP), the Conservation Stewardship Program (CSP), and the newer Conservation Loan Program (CLP).[34] While these conservation and energy programs are the most important sources of federal funds for manure biogas, many other programs support the development of the industry. The 2018 Farm Bill's Energy Title alone includes the Biorefinery, Renewable Chemical, and Biobased Product Manufacturing Assistance Program;[35] the Bioenergy Program for Advanced Biofuels;[36] Biomass Research and Development Program;[37] the Biodiesel Fuel Education Program;[38] and the Carbon Utilization and Biogas Education Program.[39]

USDA encourages livestock operations to "stack" multiple programs. In 2015, USDA stated:



> To coordinate and maximize the potential assistance programs, Rural Development (RD) and Natural Resources Conservation Service (NRCS) met and developed a working partnership to deliver USDA services to producers interested in getting an anaerobic digester for their farming operation…. When "stacking," both RD and NRCS funding mechanisms can be used to assist in funding a project but each has limitations; for instance, the $450,000 cap on EQIP encompasses financial assistance for any practice that the producer wants to implement during the life of the Farm Bill.[40]

The report encourages the 50-50 use of EQIP and REAP funds and provides a detailed breakdown of estimated costs, where the two programs cover the total $1,778,950 required to construct the digester system.

Some states provide a similar suite of programs to fund the installation of manure biogas systems. In California, for example, the Dairy Digester Research & Development Program (DDRDP) provides funding for the installation of dairy digesters.[41] There are many smaller programs that offer grants, such as the Minnesota Department of Agriculture's Methane Digester Loan Program.[42]

The federal 1603 program, "Payments for Specified Energy Property in Lieu of Tax Credits,"[43] provides grants to reimburse businesses for a portion of the cost of installing certain energy projects, including anaerobic digesters on farms.[44] The 1603 program's creation as part of the American Recovery and Reinvestment Act in 2009 was "motivated by difficult economic conditions and the perceived lack of tax-equity capacity to support renewable energy projects" eligible for the tax credits discussed below.[45] While most 1603 funding has gone to wind and solar projects,[46] the program has provided funding for at least 98 projects designated "biomass (open loop, livestock)" for a total of $119,133,949.00 or an average of $1,215,652.54 per operation.[47]

1603 PROGRAM:
Payments for Specified Energy Property in Lieu of Tax Credits

Private investment is also available to livestock operations seeking funding to install digester systems. As public programs to subsidize manure biogas production proliferate, the industry has become increasingly appealing to private investors. A March 2021 report by Stifel Equity Research laid out the prospects for manure biogas as follows:

> We are bullish on the fundamentals of renewable natural gas (RNG) as it is positive for the environment (net negative carbon form of energy post-combustion), it is economic today (10-60 percent project IRRs), and offers immense growth potential (IEA projects an 18x increase in supply by 2040).[48]

The report noted that the current optimistic forecast for investors is closely linked to the enormous policy supports for this technology:[49]

> The combination of policy ([CA] Senate Bill 1383, requiring reductions in short-lived climate pollutants) and regulatory incentives (both federal and state) have driven the recent inflection in RNG growth. In our view, producers are not in the business of producing RNG; they are in the business of monetizing RNG's environmental attributes through various federal and state programs.[50]

Subsidies & Other Programs That Enhance Revenue from Biogas Sales

In addition to funding sources intended to help livestock operators cover the fixed costs of biogas system construction, state and federal programs subsidize the revenue from biogas production on an ongoing basis.

The Federal Renewable Fuel Standard (RFS), which requires transportation fuels sold in the United States to contain a minimum amount of renewable fuel (a "Renewable Volume Obligation"), is a key source of potential revenue for manure biogas operations. The RFS is a market-based program intended to reduce overall emissions from transportation fuels in the United States. It is structured like a cap-and-trade program, but rather than cap net GHG emissions, the RFS mandates a quota for the amount of renewable fuel that must be incorporated into conventional transportation fuels.

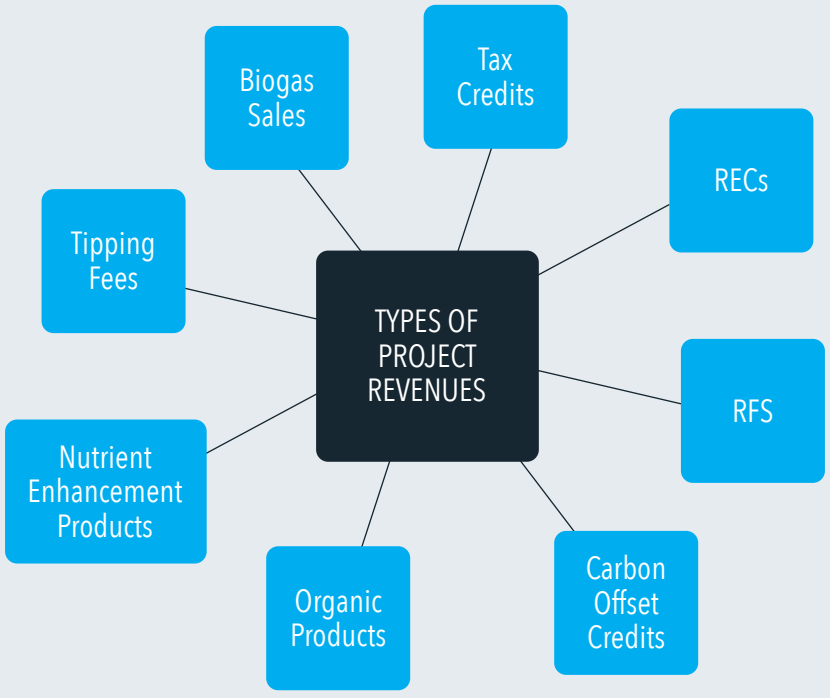
EPA measures the emissions impact of each eligible renewable fuel through the evaluation of fuel "pathways."[51] The pathway for each renewable fuel describes the inputs and processes required, as well as the life cycle GHGs.[52] Renewable fuel producers then apply to EPA for the specific pathways to which their fuel product corresponds. Once approved, these fuel producers can generate renewable identification numbers (RINs), which allow EPA to track and monitor these fuels.[53] Renewable fuels and their corresponding RINs can be sold to producers of conventional fuels so they can meet the quota required by the RFS. Biogas from manure digesters can be used to generate advanced biofuel RINs, coded D5 in the RFS regulation.[54] (77,000 British thermal units are equal to one gallon equivalent or one RIN.[55]) RINs are explicitly allowed to be layered on top of other analogous credits, such as those from California's Low Carbon Fuel Standard.[56]

Meeting the Federal Renewable Fuel Standard (RFS)

EPA measures the emissions impact of renewable fuels by evaluating their fuel "pathway," or the processes required to produce them. Biogas from manure digesters can be used to generate advanced biofuel renewable identification numbers (RINs).

Renewable fuel producers apply to EPA for their product's specific pathway.

Approved fuel producers generate RINs so EPA can track and monitor their fuels.



RINs can be sold to conventional fuel producers, allowing them to meet the Renewable Fuel Standard.

The federal Advanced Biofuel Payment Program also subsidizes biogas revenue. The program provides quarterly payments "for the actual quantity of eligible advanced biofuel produced during that quarter" to biofuel producers, including refined biogas from farms.[57] Entities that produce and sell biofuels, as defined in 7 CFR § 4288.102, can apply to participate in the program.[58] This program was granted $322,000,000 in mandatory funding between 2009 and 2023, in addition to $80,000,000 of discretionary funding authorized to be appropriated for the program between 2019 and 2023.[59]

In addition to direct payments, the federal government provides tax credits through the Electricity Production Credit and the Investment Tax Credit. Both corporate tax credits reduce energy producers' tax burdens, but while the Electricity Production Credit compensates producers on a per kilowatt-hour basis for renewable energy (including "open-loop biomass"), the Investment Tax Credit reimburses a set percentage of installation costs.[60] Importantly, taxpayers must choose either the Electricity Production Credit or the Investment Tax Credit—they cannot apply for both.

TYPES OF PROJECT REVENUES

Source: AgSTAR Project Development Handbook, Environmental Protection Agency

[61]

At the state level, the Biofuels Investment Tax Credit also allowed companies in Florida to recoup "75% of all capital, operation, maintenance, and research and development costs incurred in connection with an investment in the production, storage, and distribution of biodiesel (B10-B100), ethanol (E10-E100), or other renewable fuel" through 2016.[62] Additionally, industry groups tout California's Low Carbon Fuel Standard (LCFS) as a boon to the biogas industry's profitability.[63] The program creates a tradeable market for credits and deficits, which are allocated to transportation fuel producers based on the carbon intensity of the fuels they produce. Low carbon intensity fuels receive credits, while high carbon intensity fuels receive deficits. Like the federal RFS, California's LCFS program currently designates manure biogas as a negative emissions fuel and, consequently, awards profitable credits for its production.[64] This revenue is allocated to producers on an ongoing basis in proportion to the quantity of fuel they produce. Biogas producers that participate in the LCFS are also explicitly allowed to participate in California's cap-and-trade program, as well as the federal RFS. Like the stacking of USDA and DOE funds described above, layering multiple credits is explicitly described as a benefit.

Ultimately, however, the layering of credits from multiple market-based programs can undermine the additionality of emissions reductions claimed by those programs. Additionality is a term of art used to evaluate whether the policy intervention in question is in fact the cause of a given real-world behavior change. A behavior is not additional if it would have happened with or without the policy intervention. Compensating or crediting nonadditional behaviors, like the production of manure biogas, risks over-incentivizing them and even increasing rather than decreasing overall emissions. While California's LCFS is the most well-developed credit trading program for transportation fuels, other states are developing similarly structured programs, including Oregon's Clean Fuels Initiative program.

Finally, some states are creating reliable markets for these fuels as a source of "renewable energy" through utilities. Where renewable fuels standards like the programs described above focus on transportation fuels, renewable portfolio standards or renewable electricity standards focus on the use of renewable energy sources for electricity generation. These programs typically mandate that a certain amount of energy be derived from renewable sources and define what constitutes renewable sources for the purposes of the program. Much like the RINs in the federal renewable fuel standard, many renewable portfolio standards at the state level implement trading programs using renewable electricity certificates (RECs). State programs vary, but they usually include manure biogas as a renewable energy source.[65]

Considered collectively, these funds represent potential windfalls for operations well suited to the installation of manure biogas systems. But, smaller, less established operations, or operations that use dry manure management systems or grazing systems are unlikely to benefit from these funds, even though their models may be more climate smart overall in accord with the Biden Administration's stated goals and objectives.

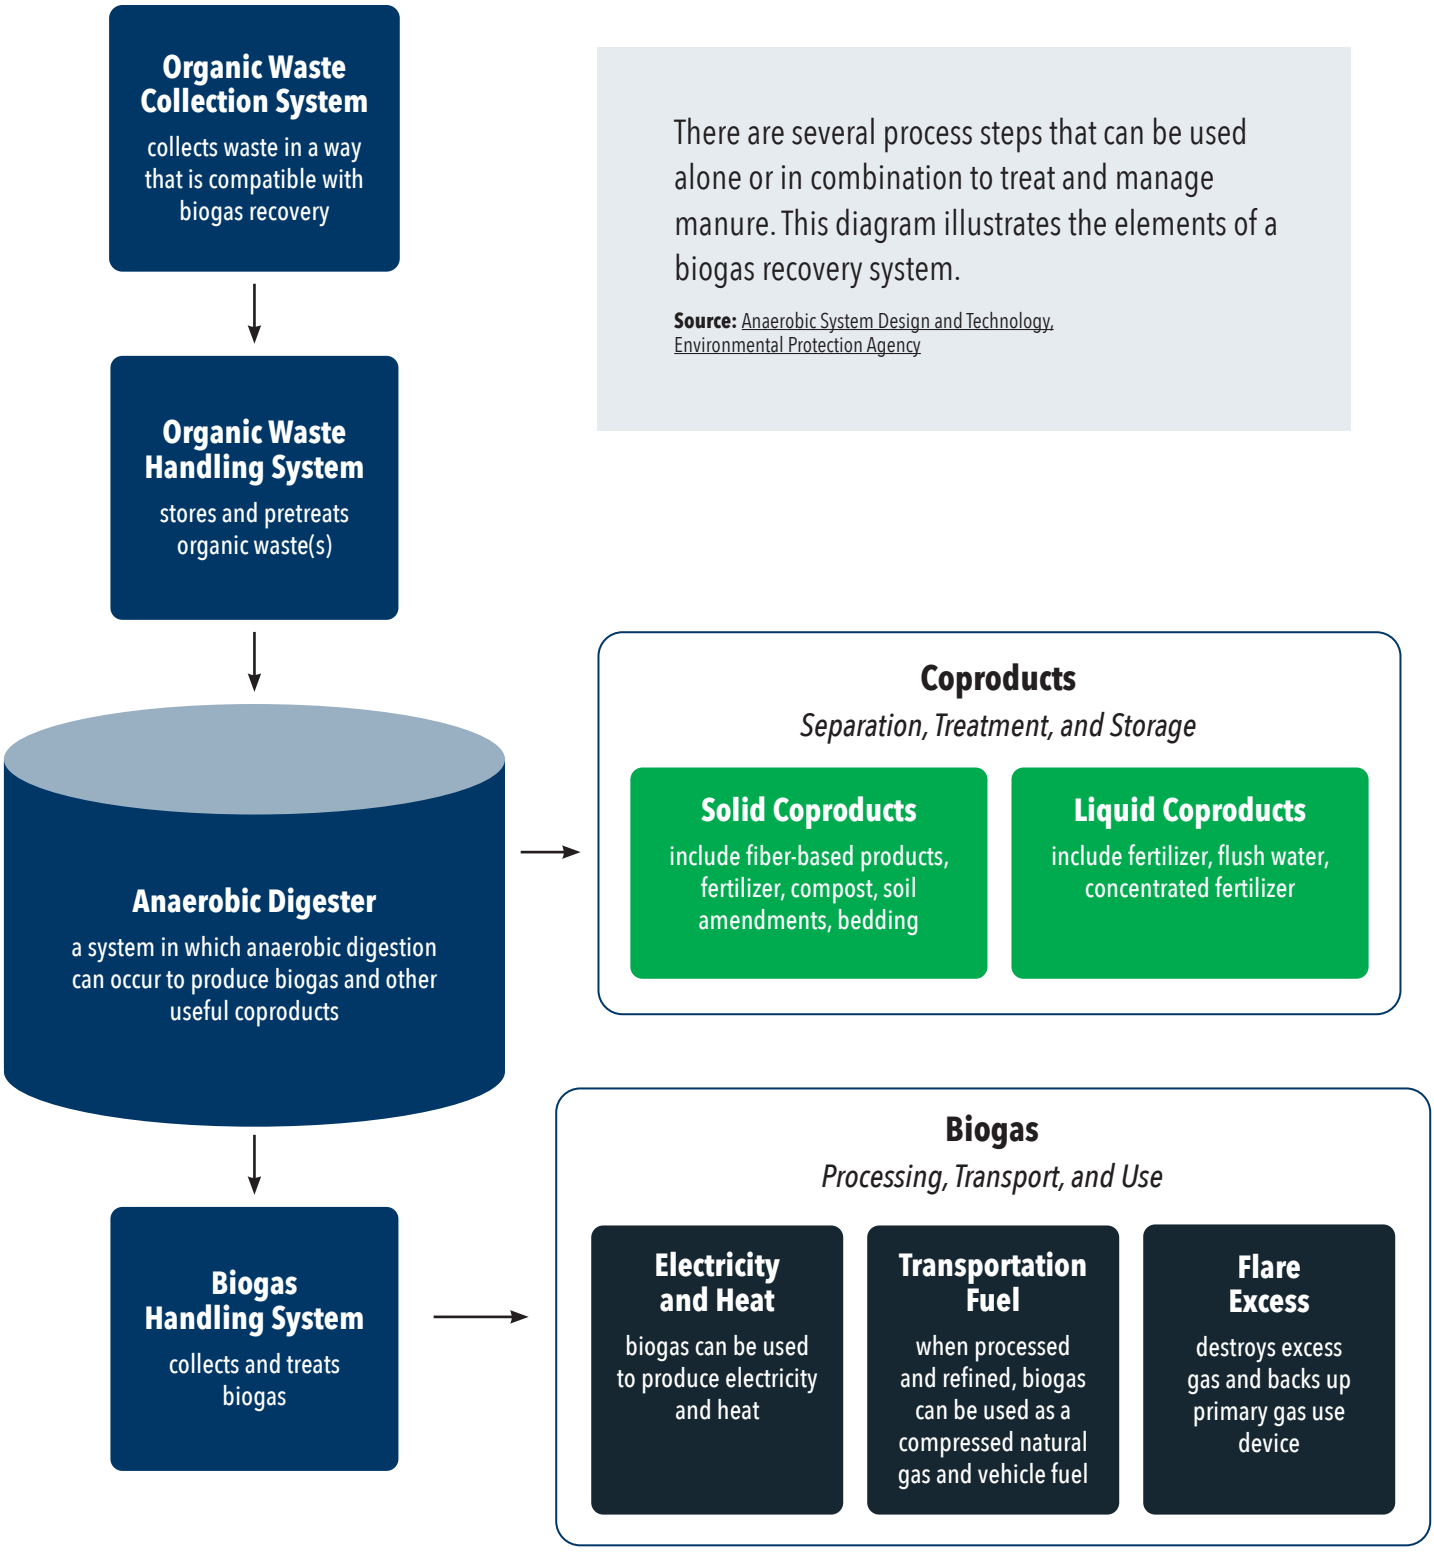
ANAEROBIC DIGESTERS CAN IMPOSE NEW ENVIRONMENTAL HARMS

TO PRODUCE BIOGAS FROM MANURE, farming operations must install an anaerobic digester, typically by capping or covering an existing manure lagoon to create an oxygen-free environment in which bacteria can break down organic matter. Biogas is a byproduct of this process. These systems offer some climate benefits (namely capturing methane and converting it to carbon dioxide during combustion) but their installation and use can also add new environmental harms. Such harms depend on a range of factors, including:



- the scale of the operations;
- the geography of the site;
- existing cumulative impacts to air and water;
- the end use of the biomethane; and
- the management of digestate (a byproduct of anaerobic digestion).

Through the process of anaerobic digestion, animal manure undergoes chemical changes that result in the production of a mix of gases, solid digestate, and liquid effluent. Biogas can be combusted to generate electricity on-site or exported as electricity and sold to the grid or at wholesale rates. The gases can be further "upgraded" to biomethane, which has a range of potential uses. Biomethane can be used on-site, injected into a pipeline, or used as a transportation fuel (when compressed to produce compressed natural gas).[66]

Through the process of anaerobic digestion, animal manure undergoes chemical changes that result in the production of a mix of gases, solid digestate, and liquid effluent.

Anaerobic System Design & Technology

There are several process steps that can be used alone or in combination to treat and manage manure. This diagram illustrates the elements of a biogas recovery system.

Source: Anaerobic System Design and Technology, Environmental Protection Agency

Biogas Systems Primarily Benefit Large Operations Using Liquid Manure Management Systems

Two of EPA's screening questions to evaluate a livestock facility's potential for anaerobic digester systems ask whether the operation is "large" and whether it uses a liquid manure management system.[67] To be financially viable, biogas recovery systems typically require manure from at least 2,000 hogs or at least 500 cows.[68] According to EPA, manure biogas projects are "most likely to succeed where manure is collected as a liquid, slurry, or semi-solid and stored in open pits, ponds, or lagoons" because liquid manure can be easily flushed into lagoons.[69] Dry manure management is more common on pasture-based operations, where there is no easy manure collection system. Industrial scale operations and liquid manure management tend to go hand-in-hand because very large facilities often cannot dispose of all of their manure safely through land application without exceeding the amount of nutrients the land can take up. Additionally, liquefaction makes manure management less costly where livestock is confined.[70] A major downside to the liquefaction of manure, however, is that it generates more GHG emissions, since the anaerobic conditions in manure lagoons produce additional methane.[71] A 2022 EPA report explains:

To be financially viable, biogas recovery systems typically require manure from at least 2,000 hogs or at least 500 cows.

> When livestock manure is stored or treated in systems that promote anaerobic conditions (e.g., as a liquid/slurry in lagoons, ponds, tanks, or pits), the decomposition of the volatile solids component in the manure tends to produce CH4 (methane). When manure is handled as a solid (e.g., in stacks or drylots) or deposited on pasture, range, or paddock lands, it tends to decompose aerobically and produce CO2 and little or no CH4.[72]

The same report tied growth in industrial animal agriculture operations that liquefy manure to the broader increase in manure-related methane and nitrous oxide emissions since 1990.[73] EPA concluded:

> In many cases, manure management systems with the most substantial methane emissions are those associated with confined animal management operations where manure is handled in liquid-based systems… The shift toward larger dairy cattle and swine facilities since 1990 has translated into an increasing use of liquid manure management systems, which have higher potential CH4 emissions than dry systems.[74]

Biogas Systems Require New Infrastructure

Depending on the desired end use of the refined biomethane produced by anaerobic digestion and subsequent refining, operations require a range of additional infrastructure. New infrastructure can introduce additional truck traffic or pipeline interconnections and result in significant wear to common infrastructure such as roads. Depending on how the biogas is to be used, on-site gas treatment systems may be necessary to process the gas accordingly. Temporary storage systems for biogas may also be required and excess biogas may need to be flared, or burned off, in some cases.

Biogas Systems Produce New Co-Pollutants & Exacerbate Existing Co-Pollutants

Anaerobic digestion creates a byproduct called digestate, which can be used as animal bedding or as fertilizer. Digestate is chemically different from the original manure. Digestate contains "more soluble plant nutrients due to mineralization and has less degradable biomass than the original substrate resulting in changes in GHG and NH3 emissions."[75] The method of storage and treatment of digestate can significantly impact the total GHG emissions from the biogas system, as well as co-pollutants like volatile organic compounds (VOCs) and hydrogen sulfide.

A 2017 study seeking to provide clarity on the emissions impact of anaerobic digestion (versus solid-liquid separation versus a combination of the two methods) found that anaerobic digestion alone resulted in an 81 percent increase in ammonia emissions during storage.[76] The authors concluded that anaerobic digestion could "significantly increase NH3 emissions from manure storage if manure covers are not implemented."[77] While ammonia is not a greenhouse gas, it

creates serious public health harms and degrades air quality.[78] The study also found that the nitrous oxide from digested separated solids "was much higher than separated solids without digestion," canceling out net GHG reductions.[79] This indicates that the simple adoption of manure biogas systems is not enough to ensure a net reduction in emissions from a given operation.

One study at a swine biogas facility in China took digestate to a research facility, stored it under controlled conditions, and then measured resulting emissions. The study identified 49 VOCs, 22 of which have been described as hazardous air pollutants by EPA. Of these 22 hazardous VOCs, "11 of these had relatively high concentrations . . . 8 were identified to be or likely to be carcinogenic, and 14 were identified to be harmful to other human organs or systems."[80] While most studies on VOCs from manure focus on the odor-causing compounds, the "proportion of hazardous air pollutants (32.77 percent) was shown to be considerably higher than that of odorous pollutants (5.15 percent)."[81]

Another study looked at manure under anaerobic conditions from two different dairy farms in Japan and found that hydrogen sulfide emissions vary considerably based on the mixing speed and frequency of disturbance of the stored manure as well as the manure's total solid content, temperature, and pH. For example, when stored at 18 degrees Celsius (64 degrees Fahrenheit), there was a sudden increase in the concentration of hydrogen sulfide (H_2S).[82] Additionally, "[the highest H_2S emissions were achieved at the fastest speed and longest duration of manure mixing."[83] Given that exposure to hydrogen sulfide is extremely dangerous and has been linked to death, the storage and treatment of manure and digestate is critical.[84]

New Impacts Must Be Evaluated in Analyses of Biogas Systems

These new impacts must be incorporated into analyses intended to evaluate the potential benefits of manure biogas systems. Unfortunately, such analyses often omit key considerations regarding co-pollutants, new infrastructure, and the environmental justice and equity implications associated with manure biogas systems. As stated above, the conventionally cited environmental benefit of manure biogas systems is a net reduction in atmospheric GHG emissions. Policy support for biogas systems rests on this reduction and as a result, life cycle analyses of manure biogas systems typically focus their impact evaluation on GHG emissions specifically and do not always address harms from co-pollutants or new infrastructure.

The metric typically used to quantify the environmental sustainability of a product or service is life cycle analysis (LCA). The goal of LCA is to provide a comprehensive view of environmental impacts to help decision-makers identify the effect of a given good or service. LCAs estimate

To properly account for the full life cycle emissions, any manure biogas LCA should include the storage and disposal of digestate, as well as the emissions generated in the production of manure, that is, the emissions resulting from raising the livestock in question.

the cumulative environmental impacts resulting from all stages of a product, process, or service through the life cycle, from raw material acquisition, manufacturing, use/reuse/maintenance, to recycling/waste management.[85] Programs like the Federal Renewable Fuel Standard and California's Low Carbon Fuel Standard, described above in part II, rely on life cycle assessments to determine the life cycle GHG emissions of participant fuels, including those derived from manure biogas systems. Both EPA and the California Air Resources Board use versions of the Greenhouse Gases, Regulated Emissions, and Energy Use in Transportation (GREET) life cycle analysis model which is designed for transportation fuels.[86]

System boundaries mark the beginning and end of the process or life cycle in question. Consequently, the boundaries and assumptions used in the LCA model are critical. For example, an LCA that excluded emissions related to digestate would not fully account for life cycle emissions of manure biogas. To properly account for the full life cycle emissions, any manure biogas LCA should include the storage and disposal of digestate, as well as the emissions generated in the production of manure, that is, the emissions resulting from raising the livestock in question.

When produced at an industrial scale, animal manure can create severe environmental harms and adverse impacts to public health. The impacts of manure include water contamination, air pollution, and foul odor (which can degrade quality of life for neighboring communities and decrease property values), in addition to GHG emissions. Manure biogas systems capture some of the emissions from livestock facilities, but fail to address the co-pollutants associated with manure production while also producing new co-pollutants from the processing and storage of the resulting digestate, as discussed above. Multiple toxic pollutants, including VOCs, ammonia, endotoxins, particulate matter, and bioaerosols are linked to large-scale industrial confined animal feeding operations.[87] To the extent that anaerobic digestion technology maintains or even expands the model of concentrated industrial animal agriculture, it can perpetuate and even increase resulting public health harms.

In many parts of the country, these impacts disproportionately harm Black, Indigenous, and low-income communities. Multiple disparity analyses (and resulting civil rights complaints submitted to regulators) have challenged states' approaches to the regulation of industrial animal agriculture. One recent complaint filed with EPA's External Civil Rights Compliance

"These harms disproportionately affect Black and Latinx people living near the Hog Operations, and it is these communities who will suffer most if pollution from the Hog Operations worsens, as is expected with the Permits. Decades of research–including research reviewed by this office–demonstrate how the lagoon and sprayfield waste management system authorized by the Permits pollute rivers, streams, and air quality throughout eastern North Carolina. Despite this, and despite evidence indicating the increased risk of pollution and adverse health impacts to nearby residents from the increases to harmful hog waste pollutants resulting from biogas production, DEQ issued the Permits without addressing these harms. This is unacceptable and a violation of federal law." – SELC complaint to EPA, 2021

Source: Southern Environmental Law Center

Office under Title VI of the Civil Rights Act alleged that North Carolina's new general permit for manure biogas exacerbated existing discriminatory impacts of the livestock industry in the state.[88] The complaint alleges that the North Carolina Department of Environmental Quality's new general permit for biogas systems on confined animal feeding operations "authorizes not only the continued use of the discriminatory lagoon and sprayfield system, but also the use of anerobic digesters and uncovered 'secondary' lagoons, which will exacerbate the underlying system's impacts on communities of color."[89] This complaint follows another civil rights complaint addressing the discriminatory harms of the hog industry in North Carolina, to which EPA responded with a letter expressing "deep concern."[90]

Typical Pollutants Found in Air Surrounding CAFOs

CAFO EMISSIONS	SOURCE	TRAITS	HEALTH RISKS
Ammonia	Formed when microbes decompose undigested organic nitrogen compounds in manure	Colorless, sharp pungent odor	Respiratory irritant, chemical burns to the respiratory tract, skin, and eyes, severe cough, chronic lung disease
Hydrogen Sulfide	Anaerobic bacterial decomposition of protein and other sulfur containing organic matter	Odor of rotten eggs	Inflammation of the moist membranes of eye and respiratory tract, olfactory neuron loss, death
Methane	Microbial degradation of organic matter under anaerobic conditions	Colorless, odorless, highly flammable	No health risks. Is a greenhouse gas and contributes to climate change
Particulate Matter	Feed, bedding materials, dry manure, unpaved soil surfaces, animal dander, poultry feathers	Comprised of fecal matter, feed materials, pollen, bacteria, fungi, skin cells, silicates	Chronic bronchitis, chronic respiratory symptoms, declines in lung function, organic dust toxic syndrome

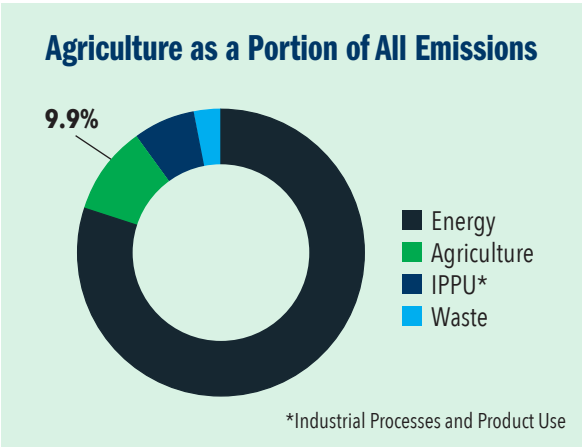
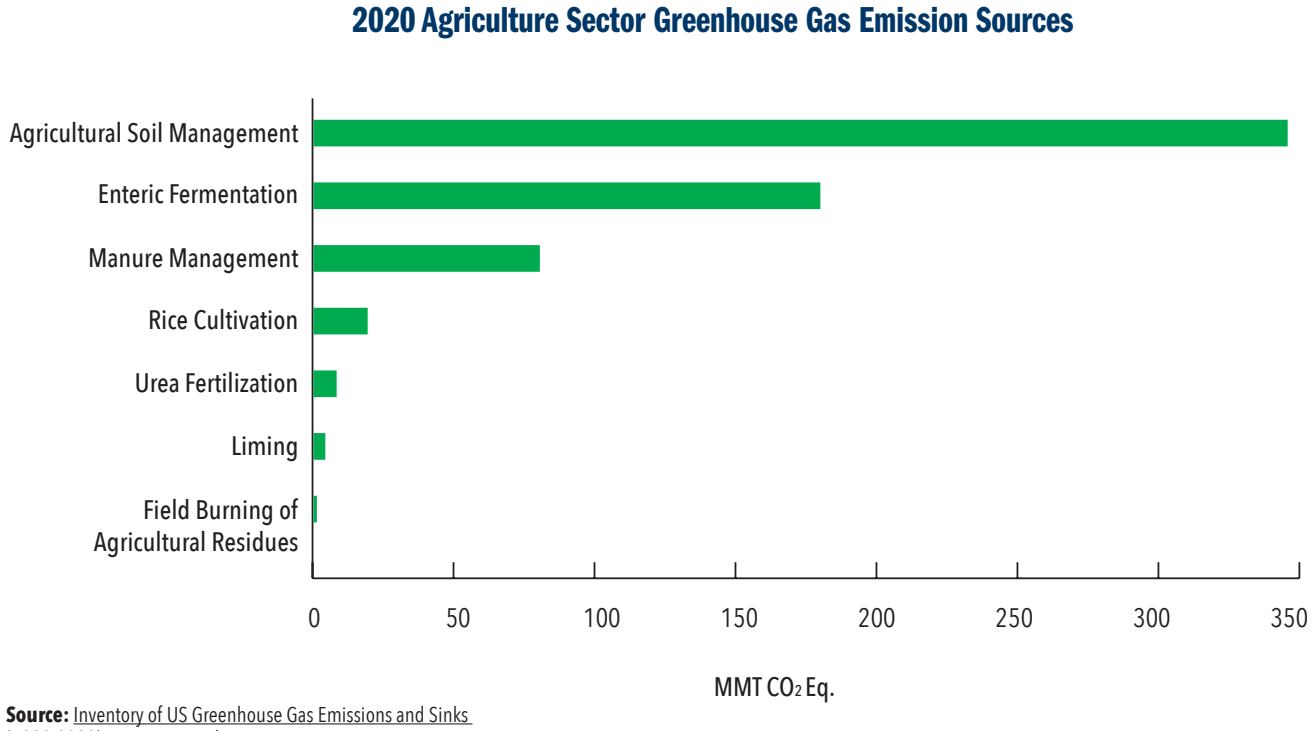
INVESTING IN MANURE BIOGAS SYSTEMS REWARDS THE LARGEST FACILITIES AND MAINTAINS THEIR UNSUSTAINABLE MODEL

THE SHEER NUMBER OF PROGRAMS designed to support the installation and operation of manure biogas systems on livestock operations presents two important questions. First, are these programs necessary to obtain the intended climate benefits of biogas systems and to what extent do they contribute to an overall emissions reduction? Second, what are the opportunity costs of the intense focus on this one method of reducing livestock emissions, given the range of alternatives? The fact that alternatives exist, coupled with the requirement that manure production continue at staggering rates to ensure the productivity of manure biogas systems calls into question whether it is prudent to focus policy efforts on a single solution.

Biogas Systems May Not Reduce Overall Emissions



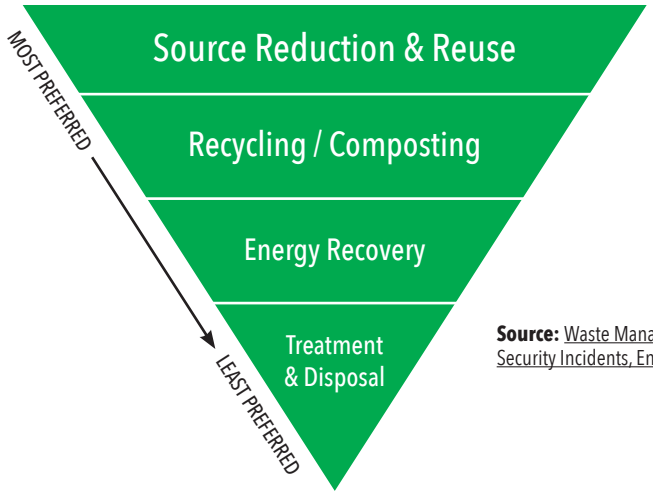
Anaerobic digesters are designed to capture (and monetize) methane and other gases that would otherwise be emitted into the air from manure lagoons. However, *capturing* emissions does not avoid or reduce emissions at the source. Reducing emissions at the source would entail significant changes in livestock production systems. Digester systems are sometimes described as stopgap measures—a means to reduce emissions quickly in the absence of developing or implementing alternative measures. However, climate science demonstrates that significant reductions at the source are required in the next decade. Investing in expensive durable infrastructure that requires ongoing manure production at current rates without emissions reductions fails to meet this imperative.



Because manure biogas systems capture rather than reduce emissions, these systems **require the ongoing generation of GHG emissions** to be financially viable. The digester's function is to capture the emissions, so the system breaks down if emissions are reduced at the source. Producers must continue to generate manure at scale for the facilities to remain financially sustainable. The large upfront investment in these systems then fixes the current numbers and concentration of livestock at facilities where they are installed, despite the range of harms

Photo source: Ag Partners, Hartley, Iowa by TumblingRun is licensed under CC BY-NC-ND 2.0.

generated by such concentrated operations. Simultaneously, the new subsidized revenue streams support the ongoing generation of manure at scale. This outcome is sharply at odds with the prescriptions of climate scientists and the Biden Administration's stated climate goals.



Additionally, while anaerobic digesters capture manure methane from lagoons, they do not capture greenhouse gas emissions before or after this point. The emissions from manure management that can be targeted by digesters make up 9.2 percent of total methane emissions from anthropogenic activities, while emissions from enteric fermentation, which remain untouched by digester systems, make up 26.9 percent.[91] In contrast, other interventions in the industrial animal agriculture system, including alternative methods of manure management and changes to animals' diet, address emissions throughout or at various points in the process of raising livestock. Importantly, a significant portion of livestock GHG emissions result from the decision to liquefy manure.[92] Some manure management emissions can be avoided by using dry manure management systems, as many farmers do. Capturing GHG emissions should be a last resort option after other alternatives have been pursued to avoid

Source: Inventory of US Greenhouse Gas Emissions and Sinks (1990-2020), Environmental Protection Agency

Waste Management Hierarchy

Source: Waste Management Hierarchy and Homeland Security Incidents, Environmental Protection Agency

or reduce emissions. This tracks with other federal policy efforts and priorities, as reduction is the management method at the top of EPA's waste management hierarchy for decision-making (organized from least to most detrimental to human and animal health and the environment).[93]

Alternative measures to reduce methane emissions from animal agriculture are available and feasible. Manure management systems generally include processes for the collection, transfer, storage, and sometimes treatment and end-use of manure.[94] Alternatives are available at each point along the way. At the initial collection stage, operations can opt for dry-scrape systems, rather than the flush systems typically used for lagoons. Dry scrape systems use mechanical scrapers to move manure into holding pits.

Livestock operations can also be designed as pasture-based, rather than confinement. On pasture-based operations, manure is typically left on pasture and produces minimal methane.[95] Pasture-based operations that rely primarily on grazing for animals' nutrition can also avoid emissions associated with the production and transportation of the feed used on confinement operations[96] and can potentially provide carbon sequestration benefits if grasslands and grazing are properly managed.[97] At the storage stage, operations can employ solid-liquid separation rather than flushing all liquefied manure directly into a lagoon. Once liquids have been separated out, manure solids can be composted.[98] A technical report prepared for the California Air Resources Board concluded that, in addition to manure biogas system installation:

> Methane emissions from lagoon storage systems can be decreased by reducing the amount or modifying anaerobic storage (i.e. solids separation and diversion from lagoon, modifying dominant flush collection to manure scraping with drying/composting or other lagoon diversion, etc.), aerating the lagoon (to reduce or eliminate anaerobic conditions).[99]

These are viable methods of manure management that would avoid, rather than simply capture, at least some emissions associated with open-air lagoons of liquid manure.[100] Many livestock operations already employ these lower-emissions practices. Unfortunately for them, however, smaller operations, pasture-based operations, or operations that have a more sustainable business model of dry manure management will not benefit from the significant public funds currently being channeled to biogas-eligible facilities. This sets a perverse precedent of neglecting historically good actors while rewarding the worst polluters in the livestock industry with new revenue and fodder for positive public relations.

Tied to the claim that biogas systems reduce emissions is the argument that the use of manure systems displaces the use of fossil fuels. An empirical analysis of this claim is beyond the scope of this report. However, regulators and policymakers should carefully consider the climate value of replacing fossil fuels with the combustion of biomethane, especially for the magnitude of public funds invested in this displacement. Renewability does not necessarily mean that a fuel is sustainable or climate friendly.[101]

Biogas Systems May Not Generate Revenue & "Design Out Waste"

Another important consideration is whether manure biogas systems really generate revenue and "design out" waste. This reflects a broader trend in policy prescriptions, sometimes referred to as the "circular economy," that seeks to "design out" waste from various industrial life cycles.[102] Proponents of the circular economy use the phrase "designing out" manure or any other waste product to mean that the waste is made profitable through other industrial processes. Unlocking new profits from waste,[103] however, does not necessarily entail any changes to the processes of waste generation or to any environmental or public health harms that arise from these processes.

In the case of manure biogas systems, manure is still produced, liquefied, and transported to manure lagoons—it must be for the biogas system to function. Anaerobic digestion does not make the manure vanish, it produces digestate. As discussed above, digestate has industrial uses, as fertilizer, for example, but also carries many of the same potential environmental harms as manure. Therefore, while it is correct to say that manure biogas systems access the potential economic value of manure as a fuel source, the waste does not disappear and can continue to cause environmental and public health harms, before, during, and after (as digestate) the process of anaerobic digestion.

While it is correct to say that manure biogas systems access the potential economic value of manure as a fuel source, the waste does not disappear and can continue to cause environmental and public health harms, before, during, and after (as digestate) the process of anaerobic digestion.

The massive quantities of manure produced at industrial scale livestock facilities can and do cause serious environmental, quality of life, and public health harms to neighboring communities. These harms do not cease to exist upon the addition of an anaerobic digester. In fact, while proponents of biogas systems sometimes argue that capping lagoons can address these issues, impacted environmental justice communities around the country have organized against the proliferation of biogas because it is viewed as maintaining and supporting a harmful system.[104]

Beyond the Baseline: Evaluating Mitigation Measures Against Policy Alternatives

The climate benefits associated with greater public resources devoted to expanding manure biogas production can only be evaluated relative to other available policy options. Such policy options cannot be limited to a business-as-usual scenario, which the scientific community has made clear is untenable. Regulators currently consider the displacement of fossil fuels when evaluating the benefits associated with these systems, but they must also consider the alternative emissions reduction strategies that are displaced now and into the future upon investment in large-scale manure biogas systems.

Unfortunately, conventional win-win claims break down when framed in the broader context of policy mechanisms available to address emissions from livestock. This is attributable to the many alternative approaches to reducing emissions from livestock facilities, some of which could reduce emissions throughout the life cycle, instead of those emitted only from

manure lagoons. The Biden Administration's plan to reduce methane names several of these alternatives, including installing "solid separators that reduce methane-producing slurries; providing conservation assistance for transitions to alternative manure management systems, such as deep pits, composting, transitions to pasture, or other practices that have a lower greenhouse gas profile."[105] Despite the administration's support of reducing methane-producing slurries on paper, funding for manure biogas systems that require methane-producing slurries to function continues to dwarf alternatives.

While it is unreasonable to expect a single policy mechanism or technology to solve all problems, there are viable alternative manure management practices and policy mechanisms to decrease emissions as well as co-pollutants in a more equitable manner. Currently, however, these programs are not being funded at nearly the same rate as manure biogas. In California, for example, the Alternative Manure Management Program (AAMP) has been funded at roughly half the rate of the Dairy Digester Research & Development Program (DDRDP) in recent years.[106]

In addition to a broad evaluation of each of these alternative mechanisms and potential policy mechanisms to promote them, it is essential to note the reason policy incentives are strictly necessary in this case—industrial livestock operations have historically been essentially exempt from any regulation of GHG emissions. It is, in fact, only this absence of regulation that makes the calculation of emissions reductions from the addition of digesters so high. The primary alternative policy mechanism should be to treat industrial livestock operations like every other industry in the country and regulate the emissions they externalize to the detriment of the public—the primary funders of manure biogas systems. Regulators should actively support farmers that engage in climate-friendly practices less likely to harm neighboring communities.

In the United States, livestock agriculture has dramatically shifted toward "large scale industrialized production systems."[107] As a result, livestock operations are producing more manure in centralized regions.[108] The storage, transportation, and land application[109] of this waste poses serious environmental risks, in addition to the GHG emissions from other parts of the livestock life cycle. Methane emissions from livestock manure are significant, but experts note that the trade-offs associated with manure management options, including the use of biodigesters, are not well studied and have not been proven to be "climate smarter."[110]

While it is unreasonable to expect a single policy mechanism or technology to solve all problems, there are viable alternative manure management practices and policy mechanisms to decrease emissions and co-pollutants in a more equitable manner.

POLICY RECOMMENDATIONS AND CONCLUSION

LIVESTOCK OPERATIONS' IMPACT ON CLIMATE CHANGE presents an opportunity for a real win-win: the US can develop policies that reduce GHG emissions from these facilities—as is required in order to mitigate the substantial impact of livestock agriculture on the climate—while simultaneously reducing the additional environmental harms many such facilities externalize into local communities. In many cases, have a discriminatory impact on the basis of race. These prerogatives are well aligned with the Biden Administration's Climate Smart Agriculture policy, Executive Order 14008, and Executive Order 13985.[111] Specifically, policymakers should consider the following:

USDA must ensure that recipients of its funding are in compliance with Title VI of the Civil Rights Act of 1964. This includes ensuring that state agencies that receive USDA funding and implement programs supporting manure biogas are developing such policies in a manner that does not disproportionately benefit white operators or disproportionately harm nearby communities on the basis of race, national origin, or color.

Evaluate USDA's programs to ensure that they do not have a disproportionate impact on the basis of race, national origin, or other protected class.

Properly account for the full climate impacts of manure biogas and ensure that emissions life cycle analyses consider the full range of upstream and downstream emissions in the manure biogas life cycle.

Move beyond business-as-usual as a point of comparison for manure biogas, which does not ensure a viable climate-smart future. The point of comparison should be the range of policy alternatives to biogas promotion, including the regulation of methane from agricultural operations.

Properly account for the full impacts of policies supporting manure biogas, including environmental, public health, and quality of life impacts from co-pollutants caused by manure.

Ensure a just transition for all, including for livestock farmers. Policy should ensure that farmers and farmworkers can make viable livelihoods while transitioning to more sustainable models.

Evaluate the efficacy of overlapping programs to ensure that public funds for manure biogas are effectively promoting new emissions reductions.

100 *See Alternative Manure Management Program*, Cal. Dep't Food and Ag., https://www.cdfa.ca.gov/oefi/AMMP/.

101 Renewability describes an energy source that is replenished over time. However, even renewable sources can contribute to climate change or impose environmental harms. For example, wood pellets used as biomass may technically be renewable but the . Similarly, a solar array may provide renewable energy and climate benefits but cause other environmental harms by destroying habitat. Policymakers evaluating a given energy source should be vigilant to avoid the all-too-common slippage between "renewable" and "climate-friendly" in order to properly identify the costs and benefits of a given intervention.

108 *Id.* at iv ("Livestock wastes are becoming more geographically concentrated in the United States, and excessive applications of the nutrients contained in manure pose risks to air and water resources.")

109 *Id.* at 29 ("Large livestock operations store substantial quantities of manure onsite. The manure is generally applied to cropland much more intensely than on smaller farms, and large volumes of manure must still be removed from the operation. High concentrations of manure–whether stored in lagoons, pits, or ponds prior to transport or application–raise the likelihood of leaching or volatilization, threatening groundwater and air quality. And farms that intensively apply manure to cropland and pasture may apply it at rates that exceed the ability of crops to absorb nutrients, with the excess nutrients transmitted to water and air resources.").

Acknowledgments

The Environmental Protection Agency would like to acknowledge the many individual and organizational contributors to this document, without whose efforts this report would not be complete. Although the complete list of researchers, government employees, and consultants who have provided technical and editorial support is too long to list here, EPA would like to thank some key contributors and reviewers whose work has significantly improved this year's report.

Within EPA's Office of Atmospheric Protection (OAP), development and compilation of emissions from fuel combustion was led by Vincent Camobreco. Sarah Roberts (EPA Office of Transportation and Air Quality) directed the work to compile estimates of emissions from mobile sources. Work on fugitive methane emissions from the Energy sector was directed by Melissa Weitz and Chris Sherry. Development and compilation of emissions estimates for the Waste sector were led by Lauren Aepli and Mausami Desai. Tom Wirth and John Steller directed work to compile estimates for the Agriculture and the Land Use, Land-Use Change, and Forestry chapters with support from Jake Beaulieu (ORD) on compiling the inventories for CO_2 and CH_4 associated with flooded lands. Development and compilation of Industrial Processes and Product Use (IPPU) CO_2, CH_4, and N_2O emissions was directed by Amanda Chiu and Vincent Camobreco. Development and compilation of emissions of HFCs, PFCs, SF_6, and NF_3 from the IPPU sector was directed by Deborah Ottinger, Dave Godwin, Stephanie Bogle, and Kersey Manliclic. Cross-cutting work was directed by Mausami Desai. We thank Bill Irving for general advice, guidance, and cross-cutting review.

We also thank Kenna Rewcastle and Martin Wolf (AAAS Science & Technology Policy Fellows hosted by the Office of Atmospheric Protection) for their advice and review in areas such as agricultural, land use, land-use change and forestry, and industrial processes and product use estimates, respectively.

Other EPA offices and programs also contributed data, analysis, and technical review for this report. The Office of Atmospheric Protection's Greenhouse Gas Reporting Program (OAP) staff facilitated aggregation and review of facility-level data for use in the Inventory, in particular aggregation of confidential business information data. The Office of Transportation and Air Quality and the Office of Air Quality Planning and Standards provided analysis for precursor estimates and review for several of the source categories (i.e., natural gas and petroleum systems) included in this report. The Office of Research and Development conducted field research and developed estimates associated with flooded lands. The Office of Land and Emergency Management also contributed analysis and research.

The Energy Information Administration and the Department of Energy contributed invaluable data and analysis on numerous energy-related topics. William Sanchez at EIA provided annual energy data that are used in fossil fuel combustion estimates. Other government agencies have contributed data as well, including the U.S. Geological Survey, the Federal Highway Administration, the Department of Transportation, the Bureau of Transportation Statistics, the Department of Commerce, the Mine Safety and Health Administration, and the National Agricultural Statistics Service.

We thank the Department of Defense (David Asiello, DoD and Matthew Cleaver of Leidos) for compiling the data on military bunker fuel use.

We thank the Federal Aviation Administration (Ralph Lovinelli and Jeetendra Upadhyay) for compiling the inventory of emissions from commercial aircraft jet fuel consumption.

We thank the United States Department of Agriculture's Office of the Chief Economist (Meg Xiarchos) for providing data on agricultural energy use.

We thank the U.S. Forest Service (Grant Domke, Brian Walters, Jim Smith and Mike Nichols) for compiling the inventories for CO_2, CH_4, and N_2O fluxes associated with forest land.

We thank the Department of Agriculture's Agricultural Research Service (Stephen Del Grosso) and the Natural Resource Ecology Laboratory and Department of Statistics at Colorado State University (Stephen Ogle, Bill Parton, F. Jay Breidt, Shannon Spencer, Alisa Keyser, Teng Liu, Ryan Scheiderer, Veronica Thompson, Doug Vander Wilt, Stephen Williams, Guhan Dheenadayalan Sivakami) for compiling the inventories for CH_4 emissions, N_2O emissions, and CO_2 fluxes associated with soils in croplands, grasslands, and settlements.

We thank the National Oceanic and Atmospheric Administration (NOAA) (Nate Herold, Ben DeAngelo and Meredith Muth), Silvestrum Climate Associates (Stephen Crooks, Lisa Schile Beers, Rebeca Brenes), the Smithsonian Environmental Research Center (J. Patrick Megonigal, James Holmquist and Meng Lu), and Florida International University (Tiffany Troxler) as well as members of the U.S. Coastal Wetland Carbon Working Group for compiling inventories of land use change, soil carbon stocks and stock change, CH_4 emissions, and N_2O emissions from aquaculture in coastal wetlands. We also thank NOAA (Stephen Montzka and Lei Hu) for information on atmospheric measurements and derived emissions of HFCs and SF_6.

We thank Marian Martin Van Pelt, Leslie Chinery, Alexander Lataille, and the full Inventory team at ICF including Diana Pape, Robert Lanza, Mollie Averyt, Larry O'Rourke, Deborah Harris, Rebecca Ferenchiak, Fiona Wissell, Bikash Acharya, Mollie Carroll, Kyle Herdegen, Hazelle Tomlin, Deep Shah, Lou Browning, Sarah Whitlock, David Landolfi, Emily Carr, Abby Wiseman, Georgia Kerkezis, Katie O'Malley, Emily Adkins, Zeyu Hu, Alex Da Silva, Shubh Jain, Alida Monaco, Kenny Yerardi, Hannah Krauss, Sophie Johnson, Leah Hartung, Molly Rickles, Audrey Ichida, Seth Hartley, Max Kaffel, Sam Pournazer, and Ajo Rabemiarisoa for technical support in compiling synthesis information across the report and preparing many of the individual analyses for specific report chapters including fluorinated emissions and fuel combustion.

We thank Eastern Research Group for their analytical support. Deborah Bartram, Kara Edquist and Tara Stout support the development of emissions estimates for wastewater. Kara Edquist, Cortney Itle, Amber Allen, Spencer Sauter, Tara Stout, and Sarah Wagner support the development of emission estimates for Manure Management, Enteric Fermentation, Peatlands (included in Wetlands Remaining Wetlands*)*, and Landfilled Yard Trimmings and Food Scraps (included in Settlements Remaining Settlements). Brandon Long, Gopi Manne, Marty Wolf, and Sarah Downes, support the development of estimates for Natural Gas and Petroleum Systems. Gopi Manne and Tara Stout support the development of emission estimates for coal mine methane.

Finally, we thank the RTI International team: Kate Bronstein, Emily Thompson, Jeff Coburn, and Keith Weitz for their analytical support in development of the estimates of emissions from landfills; Jason Goldsmith, Melissa Icenhour, Michael Laney, David Randall, Gabrielle Raymond, Karen Schaffner, Riley Vanek, Ricky Strott, Libby Robinson, Matt Hakos, and Jeremy Kaelin for their analytical support in development of IPPU CO_2, CH_4, and N_2O emissions; and Tiffany Moore and Matt Hakos for their analytical support on disaggregating industrial sector fossil fuel combustion emissions.

Preface

The United States Environmental Protection Agency (EPA) prepares the official U.S. Inventory of Greenhouse Gas Emissions and Sinks to fulfill annual existing commitments under the United Nations Framework Convention on Climate Change (UNFCCC). Under UNFCCC Article 4 and decisions at the First, Second, Fifth and Nineteenth Conference of Parties, national inventories for UNFCCC Annex I parties should be provided to the UNFCCC Secretariat each year by April 15.

In an effort to engage the public and researchers across the country, the EPA has instituted an annual public review and comment process for this document. The availability of the draft document on the EPA Greenhouse Gas Emissions web site was announced via Federal Register Notice. The public comment period covered a 30-day period from February 15 through March 17, 2023, and comments received during the public review period were posted to the docket EPA-HQ-OAR-2023-0001. Comments received after the closure of the public comment period will be considered for the next edition of this annual report. Responses to comments are typically posted to EPA's website 2-4 weeks following publication of the final report in April 2023.

Table of Contents

TABLE OF CONTENTS ..... **VI**

LIST OF TABLES, FIGURES, BOXES, AND EQUATIONS ..... **X**

EXECUTIVE SUMMARY **ES-1**

ES.1 Background Information ES-2

ES.2 Recent Trends in U.S. Greenhouse Gas Emissions and Sinks ES-4

ES.3 Overview of Sector Emissions and Trends ES-16

ES.4 Other Information ES-21

1. INTRODUCTION **1-1**

1.1 Background Information 1-3

1.2 National Inventory Arrangements 1-12

1.3 Inventory Process 1-14

1.4 Methodology and Data Sources 1-17

1.5 Key Categories 1-18

1.6 Quality Assurance and Quality Control (QA/QC) 1-24

1.7 Uncertainty Analysis of Emission Estimates 1-29

1.8 Completeness 1-32

1.9 Organization of Report 1-32

2. TRENDS IN GREENHOUSE GAS EMISSIONS AND REMOVALS **2-1**

2.1 Overview of U.S. Greenhouse Gas Emissions and Sinks Trends 2-1

2.2 Emissions by Economic Sector 2-28

2.3 Precursor Greenhouse Gas Emissions (CO, NO_x, NMVOCs, and SO_2) 2-40

3. ENERGY **3-1**

3.1 Fossil Fuel Combustion (CRF Source Category 1A) 3-7

3.2 Carbon Emitted from Non-Energy Uses of Fossil Fuels (CRF Source Category 1A) 3-50

3.3 Incineration of Waste (CRF Source Category 1A5) 3-58

3.4 Coal Mining (CRF Source Category 1B1a) 3-62

3.5 Abandoned Underground Coal Mines (CRF Source Category 1B1a) 3-70

3.6 Petroleum Systems (CRF Source Category 1B2a) 3-75
3.7 Natural Gas Systems (CRF Source Category 1B2b) 3-92
3.8 Abandoned Oil and Gas Wells (CRF Source Categories 1B2a and 1B2b) 3-111
3.9 International Bunker Fuels (CRF Source Category 1: Memo Items) 3-116
3.10 Biomass and Biofuels Consumption (CRF Source Category 1A) 3-121
3.11 Energy Sources of Precursor Greenhouse Gases 3-125
4. INDUSTRIAL PROCESSES AND PRODUCT USE 4-1
4.1 Cement Production (CRF Source Category 2A1) 4-10
4.2 Lime Production (CRF Source Category 2A2) 4-14
4.3 Glass Production (CRF Source Category 2A3) 4-20
4.4 Other Process Uses of Carbonates (CRF Source Category 2A4) 4-25
4.5 Ammonia Production (CRF Source Category 2B1) 4-29
4.6 Urea Consumption for Non-Agricultural Purposes 4-35
4.7 Nitric Acid Production (CRF Source Category 2B2) 4-38
4.8 Adipic Acid Production (CRF Source Category 2B3) 4-43
4.9 Caprolactam, Glyoxal and Glyoxylic Acid Production (CRF Source Category 2B4) 4-47
4.10 Carbide Production and Consumption (CRF Source Category 2B5) 4-51
4.11 Titanium Dioxide Production (CRF Source Category 2B6) 4-55
4.12 Soda Ash Production (CRF Source Category 2B7) 4-59
4.13 Petrochemical Production (CRF Source Category 2B8) 4-62
4.14 HCFC-22 Production (CRF Source Category 2B9a) 4-70
4.15 Carbon Dioxide Consumption (CRF Source Category 2B10) 4-73
4.16 Phosphoric Acid Production (CRF Source Category 2B10) 4-77
4.17 Iron and Steel Production (CRF Source Category 2C1) and Metallurgical Coke Production 4-81
4.18 Ferroalloy Production (CRF Source Category 2C2) 4-93
4.19 Aluminum Production (CRF Source Category 2C3) 4-98
4.20 Magnesium Production and Processing (CRF Source Category 2C4) 4-105
4.21 Lead Production (CRF Source Category 2C5) 4-111
4.22 Zinc Production (CRF Source Category 2C6) 4-114
4.23 Electronics Industry (CRF Source Category 2E) 4-120
4.24 Substitution of Ozone Depleting Substances (CRF Source Category 2F) 4-139
4.25 Electrical Transmission and Distribution (CRF Source Category 2G1) 4-148
4.26 Nitrous Oxide from Product Uses (CRF Source Category 2G3) 4-160
4.27 Industrial Processes and Product Use Sources of Precursor Gases 4-164
5. AGRICULTURE 5-1

5.1 Enteric Fermentation (CRF Source Category 3A) 5-4
5.2 Manure Management (CRF Source Category 3B) 5-12
5.3 Rice Cultivation (CRF Source Category 3C) 5-21
5.4 Agricultural Soil Management (CRF Source Category 3D) 5-28
5.5 Liming (CRF Source Category 3G) 5-48
5.6 Urea Fertilization (CRF Source Category 3H) 5-51
5.7 Field Burning of Agricultural Residues (CRF Source Category 3F) 5-53
6. LAND USE, LAND-USE CHANGE, AND FORESTRY 6-1
6.1 Representation of the U.S. Land Base 6-9
6.2 Forest Land Remaining Forest Land (CRF Category 4A1) 6-25
6.3 Land Converted to Forest Land (CRF Source Category 4A2) 6-49
6.4 Cropland Remaining Cropland (CRF Category 4B1) 6-56
6.5 Land Converted to Cropland (CRF Category 4B2) 6-68
6.6 Grassland Remaining Grassland (CRF Category 4C1) 6-76
6.7 Land Converted to Grassland (CRF Category 4C2) 6-88
6.8 Wetlands Remaining Wetlands (CRF Category 4D1) 6-96
6.9 Land Converted to Wetlands (CRF Source Category 4D2) 6-139
6.10 Settlements Remaining Settlements (CRF Category 4E1) 6-161
6.11 Land Converted to Settlements (CRF Category 4E2) 6-182
6.12 Other Land Remaining Other Land (CRF Category 4F1) 6-189
6.13 Land Converted to Other Land (CRF Category 4F2) 6-189
7. WASTE 7-1
7.1 Landfills (CRF Source Category 5A1) 7-4
7.2 Wastewater Treatment and Discharge (CRF Source Category 5D) 7-22
7.3 Composting (CRF Source Category 5B1) 7-57
7.4 Anaerobic Digestion at Biogas Facilities (CRF Source Category 5B2) 7-61
7.5 Waste Incineration (CRF Source Category 5C1) 7-67
7.6 Waste Sources of Precursor Greenhouse Gases 7-68
8. OTHER 8-1
9. RECALCULATIONS AND IMPROVEMENTS 9-1
10. REFERENCES AND ABBREVIATIONS 10-1

Executive Summary

An inventory that identifies and quantifies a country's anthropogenic[1] sources and sinks of greenhouse gas emissions and removals is essential for addressing climate change. This Inventory adheres to both (1) a comprehensive and detailed set of methodologies for estimating national sources and sinks of anthropogenic greenhouse gases, and (2) a common and consistent format that enables Parties to the United Nations Framework Convention on Climate Change (UNFCCC) to compare the relative contribution of different emission sources and greenhouse gases to climate change.

In 1992, the United States signed and ratified the UNFCCC. As stated in Article 2 of the UNFCCC, "The ultimate objective of this Convention and any related legal instruments that the Conference of the Parties may adopt is to achieve, in accordance with the relevant provisions of the Convention, stabilization of greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system. Such a level should be achieved within a time-frame sufficient to allow ecosystems to adapt naturally to climate change, to ensure that food production is not threatened and to enable economic development to proceed in a sustainable manner."[2]

As a signatory to the UNFCCC, consistent with Article 4[3] and decisions at the First, Second, Fifth, and Nineteenth Conference of Parties,[4] the United States is committed to submitting a national inventory of anthropogenic sources and sinks of greenhouse gases to the UNFCCC by April 15 of each year. The United States views this report, in conjunction with Common Reporting Format (CRF) reporting tables that accompany this report, as an opportunity to fulfill this annual commitment under the UNFCCC.

This executive summary provides the latest information on U.S. anthropogenic greenhouse gas emission trends from 1990 through 2021. The structure of this report is consistent with the UNFCCC guidelines for inventory reporting, as discussed in Box ES-1.[5]

---

[1] The term "anthropogenic," in this context, refers to greenhouse gas emissions and removals that are a direct result of human activities or are the result of natural processes that have been affected by human activities (IPCC 2006).

[2] Article 2 of the Framework Convention on Climate Change published by the UNEP/WMO Information Unit on Climate Change. See http://unfccc.int.

[3] Article 4(1)(a) of the United Nations Framework Convention on Climate Change (also identified in Article 12) and subsequent decisions by the Conference of the Parties elaborated the role of Annex I Parties in preparing national inventories. Article 4 states "Parties to the Convention, by ratifying, shall develop, periodically update, publish and make available…national inventories of anthropogenic emissions by sources and removals by sinks of all greenhouse gases not controlled by the Montreal Protocol, using comparable methodologies…" See http://unfccc.int for more information.

Box ES-1: Methodological Approach for Estimating and Reporting U.S. Emissions and Removals, including Relationship to EPA's Greenhouse Gas Reporting Program

In following the UNFCCC requirement under Article 4.1 and related decisions to develop and submit annual national greenhouse gas emission inventories, the emissions and removals presented in this report and this chapter are organized by source and sink categories and calculated using internationally accepted methods provided by the IPCC in the *2006 IPCC Guidelines for National Greenhouse Gas Inventories (2006 IPCC Guidelines)* and where appropriate, its supplements and refinements. Additionally, the calculated emissions and removals in a given year for the United States are presented in a common manner in line with the UNFCCC reporting guidelines for the reporting of inventories under this international agreement. The use of consistent methods to calculate emissions and removals by all nations providing their inventories to the UNFCCC ensures that these reports are comparable (UNFCCC 2014). The presentation of emissions and removals provided in this Inventory does not preclude alternative examinations, but rather this Inventory presents emissions and removals in a common format consistent with how countries are to report inventories under the UNFCCC. The report itself, and this chapter, follows this standardized format, and provides an explanation of the application of methods used to calculate emissions and removals.

EPA also collects greenhouse gas emissions data from individual facilities and suppliers of certain fossil fuels and industrial gases through its Greenhouse Gas Reporting Program (GHGRP), which is complementary to the U.S. Inventory.[6] The GHGRP applies to direct greenhouse gas emitters, fossil fuel suppliers, industrial gas suppliers, and facilities that inject carbon dioxide (CO_2) underground for sequestration or other reasons and requires reporting by over 8,000 sources or suppliers in 41 industrial categories.[7] Annual reporting is at the facility level, except for certain suppliers of fossil fuels and industrial greenhouse gases. In general, the threshold for reporting is 25,000 metric tons or more of CO_2 Eq. per year. Facilities in most source categories subject to GHGRP began reporting for the 2010 reporting year while additional types of industrial operations began reporting for reporting year 2011. Methodologies used in EPA's GHGRP are consistent with the *2006 IPCC Guidelines*. While the GHGRP does not provide full coverage of total annual U.S. greenhouse gas emissions and sinks (e.g., the GHGRP excludes emissions from the agricultural, land use, and forestry sectors), it is an important input to the calculations of national-level emissions in this Inventory.

The GHGRP dataset provides not only annual emissions information, but also other annual information such as activity data and emission factors that can improve and refine national emission estimates over time. GHGRP data also allow EPA to disaggregate national inventory estimates in new ways that can highlight differences across regions and sub-categories of emissions, along with enhancing the application of QA/QC procedures and assessment of uncertainties. See Annex 9 for more information on specific uses of GHGRP data in the Inventory (e.g., use of Subpart W data in compiling estimates for natural gas systems).

ES.1 Background Information

Greenhouse gases absorb infrared radiation, trapping heat in the atmosphere and making the planet warmer. The most important greenhouse gases directly emitted by humans include carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), and several fluorine-containing halogenated substances (HFCs, PFCs, SF_6 and NF_3). Although CO_2, CH_4, and N_2O occur naturally in the atmosphere, human activities have changed their atmospheric

[6] On October 30, 2009 the EPA promulgated a rule requiring annual reporting of greenhouse gas data from large greenhouse gas emissions sources in the United States. Implementation of the rule, codified at 40 CFR Part 98, is referred to as EPA's Greenhouse Gas Reporting Program (GHGRP).

[7] See http://www.epa.gov/ghgreporting and http://ghgdata.epa.gov/ghgp/main.do.

concentrations. From the pre-industrial era (i.e., ending about 1750) to 2021, concentrations of these greenhouse gases have increased globally by 48.1, 170.8, and 23.8 percent, respectively (IPCC 2013; NOAA/ESRL 2023a, 2023b, 2023c). This annual report estimates the total national greenhouse gas emissions and removals associated with human activities across the United States.

Global Warming Potentials

The IPCC developed the global warming potential (GWP) concept to compare the ability of a greenhouse gas to trap heat in the atmosphere relative to another gas. The GWP of a greenhouse gas is defined as the ratio of the accumulated radiative forcing within a specific time horizon caused by emitting 1 kilogram of the gas, relative to that of the reference gas CO_2 (IPCC 2013); therefore, CO_2-equivalent emissions are provided in million metric tons of CO_2 equivalent (MMT CO_2 Eq.) for non-CO_2 greenhouse gases.[8,9] All estimates are provided throughout the main report in both CO_2 equivalents and unweighted units, while estimates for all gases in this Executive Summary are presented in units of MMT CO_2 Eq. Emissions by gas in unweighted mass kilotons are also provided in the Trends and sector chapters of this report and in the Common Reporting Format (CRF) tables that are included in the submission to the UNFCCC.

Recent decisions under the UNFCCC[10] require Parties to use 100-year GWP values from the IPCC *Fifth Assessment Report* (AR5) for calculating CO_2-equivalents in their national reporting (IPCC 2013) by the end of 2024. This reflects updated science and ensures that national greenhouse gas inventories reported by all nations are comparable. In preparation for upcoming UNFCCC requirements,[11] this report reflects CO_2-equivalent greenhouse gas emission totals using 100-year AR5 GWP values. A comparison of emission values with the previously used 100-year GWP values from the IPCC *Fourth Assessment Report* (AR4) (IPCC 2007), and the IPCC *Sixth Assessment Report* (AR6) (IPCC 2021) values can be found in Annex 6.1 of this report. The 100-year GWP values used in this report are listed below in Table ES-1.

Table ES-1: Global Warming Potentials (100-Year Time Horizon) Used in this Report

Gas	GWP
CO_2	1
CH_4[a]	28
N_2O	265
HFCs	up to 12,400
PFCs	up to 11,100
SF_6	23,500
NF_3	16,100
Other Fluorinated Gases	See Annex 6

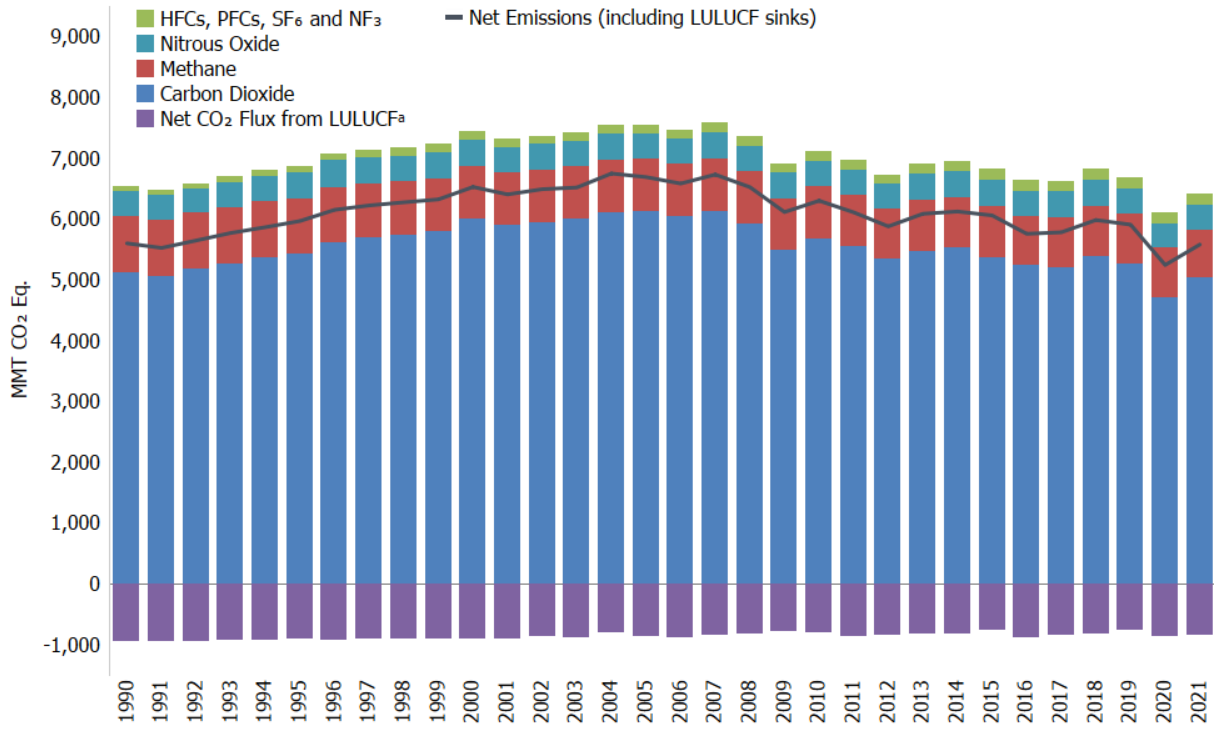
[a] The GWP of CH_4 includes the direct effects and those indirect effects due to the production of tropospheric ozone and stratospheric water vapor. The indirect effect due to production of CO_2 is not included. See Annex 6 for additional information.
Source: IPCC (2013).

[8] Carbon comprises 12/44 of carbon dioxide by weight.

[9] One million metric ton is equal to 10^{12} grams or one teragram.

[10] See paragraphs 1 and 2 of the decision on common metrics adopted at the 27th UNFCCC Conference of Parties (COP27), available online at https://unfccc.int/sites/default/files/resource/cp2022_10a01_adv.pdf.

[11] See Annex to decision 18/CMA.1, available online at https://unfccc.int/sites/default/files/resource/CMA2018_03a02E.pdf.



ES.2 Recent Trends in U.S. Greenhouse Gas Emissions and Sinks

In 2021, total gross U.S. greenhouse gas emissions were 6,340.2 million metric tons of carbon dioxide equivalent (MMT CO_2 Eq.).[12] Total U.S. emissions have decreased by 2.3 percent from 1990 to 2021, down from a high of 15.8 percent above 1990 levels in 2007. Emissions increased from 2020 to 2021 by 5.2 percent (314.3 MMT CO_2 Eq.). Net emissions (including sinks) were 5,586.0 MMT CO_2 Eq. in 2021. Overall, net emissions increased 6.4 percent from 2020 to 2021 and decreased 16.6 percent from 2005 levels as shown in Table ES-2. From 2019 to 2020, there was a sharp decline in emissions largely due to the impacts of the coronavirus (COVID-19) pandemic on travel and other economic activity. Between 2020 and 2021, the increase in total greenhouse gas emissions was driven largely by an increase in CO_2 emissions from fossil fuel combustion due to economic activity rebounding after the height of the COVID-19 pandemic. In 2021, CO_2 emissions from fossil fuel combustion increased by 6.8 percent relative to the previous year. Carbon dioxide emissions from natural gas use increased by 8.6 MMT CO_2 Eq., a 0.5 percent increase from 2020. In a shift from recent trends, CO_2 emissions from coal consumption increased by 121.7 MMT CO_2 Eq., a 14.6 percent increase from 2020. The increase in natural gas consumption and emissions in 2021 is observed across all sectors except the Electric Power sector and U.S. Territories, while the coal increase is primarily in the Electric Power sector. Emissions from petroleum use also increased by 163.9 MMT CO_2 Eq. (8.6 percent) from 2020 to 2021. In 2021, CO_2 emissions from fossil fuel combustion were 4,639.1 MMT CO_2 Eq., or 1.9 percent below emissions in 1990.

Figure ES-1 and Figure ES-2 illustrate the overall trends in total U.S. emissions by gas, annual percent changes, and relative change since 1990 for each year of the time series, and Table ES-2 provides information on trends in gross U.S. greenhouse gas emissions and sinks for 1990 through 2021. Unless otherwise stated, all tables and figures provide total gross emissions and exclude the greenhouse gas fluxes from the Land Use, Land-Use Change, and Forestry (LULUCF) sector. For more information about the LULUCF sector, see Section ES.3 Overview of Sector Emissions and Trends.

[12] The gross emissions total presented in this report for the United States excludes emissions and removals from Land Use, Land-Use Change, and Forestry (LULUCF). The net emissions total presented in this report for the United States includes emissions and removals from LULUCF.

Figure ES-1: U.S. Greenhouse Gas Emissions and Sinks by Gas

[a] The term "flux" is used to describe the exchange of CO_2 to and from the atmosphere, with net flux being either positive or negative depending on the overall balance. Removal and long-term storage of CO_2 from the atmosphere is also referred to as "carbon sequestration."

Table ES-2: Recent Trends in U.S. Greenhouse Gas Emissions and Sinks (MMT CO_2 Eq.)

Gas/Source	1990	2005	2017	2018	2019	2020	2021
CO_2	5,121.0	6,132.2	5,212.2	5,377.8	5,262.1	4,714.6	5,032.2

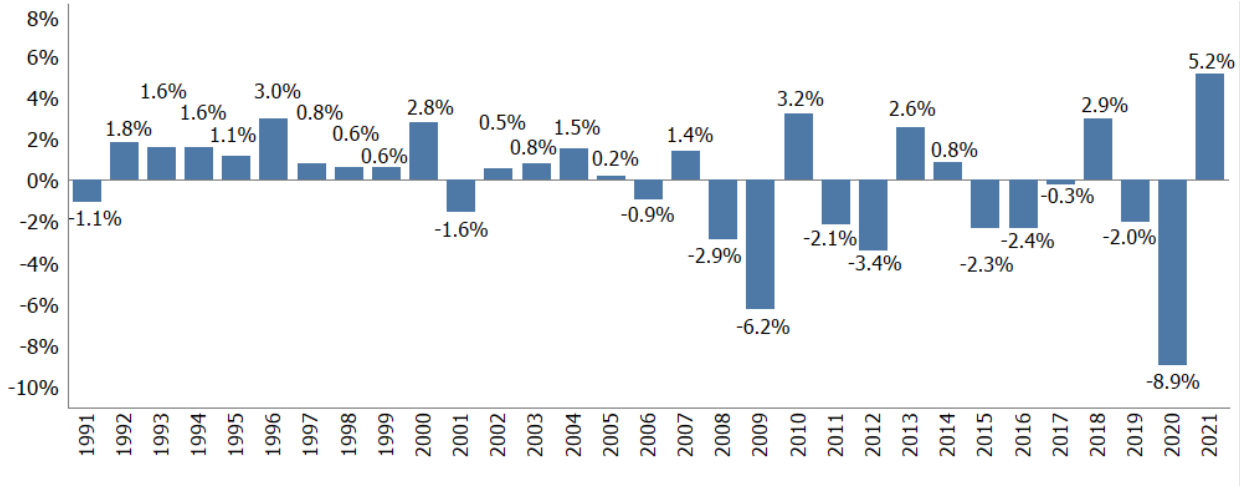
SF_6	30.5	15.5	7.2	7.1	7.8	7.5	8.0
NF_3	+	0.4	0.5	0.5	0.5	0.6	0.6
Total Gross Emissions (Sources)	**6,487.3**	**7,477.4**	**6,561.8**	**6,754.8**	**6,617.9**	**6,026.0**	**6,340.2**
LULUCF Emissions[a]	57.9	72.4	68.3	64.4	64.2	76.4	77.8
CH_4	53.5	61.3	60.1	57.3	56.9	65.4	66.0
N_2O	4.4	11.1	8.3	7.0	7.3	11.0	11.8
LULUCF Carbon Stock Change[b]	(938.9)	(853.5)	(842.5)	(829.5)	(768.2)	(852.5)	(832.0)
LULUCF Sector Net Total[c]	(881.0)	(781.1)	(774.2)	(765.1)	(704.0)	(776.2)	(754.2)
Net Emissions (Sources and Sinks)	**5,606.4**	**6,696.3**	**5,787.6**	**5,989.7**	**5,913.9**	**5,249.8**	**5,586.0**

+ Does not exceed 0.05 MMT CO_2 Eq.



[a] LULUCF emissions subtotal of CH_4 and N_2O are reported separately from gross emissions totals. LULUCF emissions include the CH_4 and N_2O emissions reported for Peatlands Remaining Peatlands, Forest Fires, Drained Organic Soils, Grassland Fires, and Coastal Wetlands Remaining Coastal Wetlands; CH_4 emissions from Land Converted to Coastal Wetlands, Flooded Land Remaining Flooded Land, and Land Converted to Flooded Land; and N_2O emissions from forest soils and settlement soils.

[b] LULUCF Carbon Stock Change is the net C stock change from the following categories: Forest Land Remaining Forest Land, Land Converted to Forest Land, Cropland Remaining Cropland, Land Converted to Cropland, Grassland Remaining Grassland, Land Converted to Grassland, Wetlands Remaining Wetlands, Land Converted to Wetlands, Settlements Remaining Settlements, and Land Converted to Settlements.

[c] The LULUCF Sector Net Total is the net sum of all LULUCF CH_4 and N_2O emissions to the atmosphere plus LULUCF net C stock changes.

Notes: Total (gross) are emissions presented without LULUCF. Net emissions are presented with LULUCF. Totals may not sum due to independent rounding. Parentheses indicate negative values or sequestration.

Figure ES-2: Annual Percent Change in Gross U.S. Greenhouse Gas Emissions and Sinks Relative to the Previous Year

Improvements and Recalculations Relative to the Previous Inventory

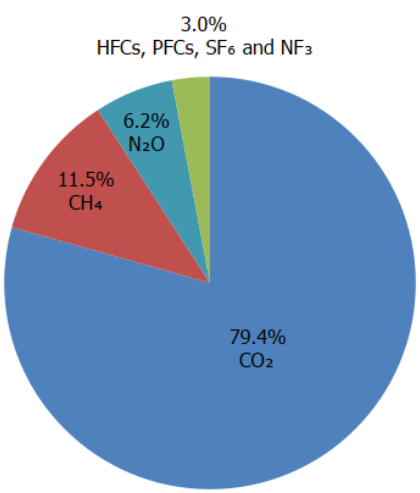
Each year, some emission and sink estimates in the Inventory are recalculated and revised to incorporate improved methods and/or data. The most common reason for recalculating U.S. greenhouse gas emission estimates is to update recent historical data. Changes in historical data are generally the result of changes in data supplied by other U.S. government agencies or organizations, as they continue to make refinements and improvements. These improvements are implemented consistently across the previous Inventory's time series, as necessary, (i.e., 1990 to 2020) to ensure that the trend is accurate. In addition, for the current Inventory, CO_2-equivalent emission estimates have been updated to reflect the 100-year GWP values provided in the IPCC *Fifth Assessment Report* (AR5) (IPCC 2013).

Below are categories with methodological and data-related recalculations[13] resulting in an average change of greater than 2.5 MMT CO_2 Eq. over the time series.

- Forest Land Remaining Forest Land: Changes in Forest Carbon Stocks (CO_2)
- Wetlands Remaining Wetlands: Emissions from Flooded Land Remaining Flooded Land (CH_4)
- Biomass and Biodiesel Consumption (CO_2)
- Agricultural Soil Management (N_2O)
- Petroleum Systems (CH_4)
- Land Converted to Grassland: Changes in all Ecosystem Carbon Stocks (CO_2)
- Land Converted to Cropland: Changes in all Ecosystem Carbon Stocks (CO_2)
- Natural Gas Systems (CH_4)

[13] This does not include the recalculations related to the update from AR4 to AR5 GWP values. For more information on the impact of that update, please see Chapter 9, Recalculations and Improvements.

In addition, the Inventory includes two new categories not included in the previous Inventory that improve completeness of the national estimates: CO_2 emissions from the Substitution of Ozone Depleting Substances and CO_2 from the biogenic components of municipal solid waste combustion (reported as a memo item in the Inventory).



In each Inventory, the results of all methodological changes and historical data updates and the inclusion of new sources and sink estimates are summarized in the Recalculations and Improvements chapter (Chapter 9). Collectively, all methodological changes and historical data updates made in the current Inventory, including the quantitative effects of updating to from use of AR4 to AR5 GWPs in calculating CO_2-equivalent U.S. greenhouse gas emissions and sink for non-CO_2 emissions resulted in an annual average increase of 43.2 MMT CO_2 Eq. (0.7 percent) for net total emissions. The impact of methodological changes and historical data updates excluding quantitative effects of updating to AR5 GWP resulted in an annual average increase of 16.1 MMT CO_2 Eq. (0.3 percent) for net total emissions. For more detailed descriptions of each recalculation including references for data, please see the respective source or sink category description(s) within the relevant report chapter (i.e., the Energy chapter [Chapter 3], the Industrial Processes and Product Use [IPPU] chapter [Chapter 4], the Agriculture chapter [Chapter 5], the Land Use, Land-Use Change, and Forestry [LULUCF] chapter [Chapter 6], and the Waste chapter [Chapter 7]). In implementing improvements, the United States follows the *2006 IPCC Guidelines* (IPCC 2006), which states,

> "Both methodological changes and refinements over time are an essential part of improving inventory quality. It is good practice to change or refine methods when: available data have changed; the previously used method is not consistent with the IPCC guidelines for that category; a category has become key; the previously used method is insufficient to reflect mitigation activities in a transparent manner; the capacity for inventory preparation has increased; new inventory methods become available; and for correction of errors."

Emissions by Gas

Figure ES-3 illustrates the relative contribution of the greenhouse gases to total gross U.S. emissions in 2021, weighted by global warming potential. The primary greenhouse gas emitted by human activities in the United States is CO_2, representing 79.4 percent of total greenhouse gas emissions. The largest source of CO_2 and of overall greenhouse gas emissions is fossil fuel combustion, primarily from transportation and power generation. Methane (CH_4) emissions account for 11.5 percent of emissions. The major sources of methane include enteric fermentation associated with domestic livestock, natural gas systems, and decomposition of wastes in landfills. Agricultural soil management, wastewater treatment, stationary sources of fuel combustion, and manure management are the major sources of N_2O emissions. Ozone depleting substance substitute emissions are the primary contributor to aggregate hydrofluorocarbon (HFC) emissions. Perfluorocarbon (PFC) emissions are primarily attributable to electronics manufacturing and primary aluminum production. Electrical transmission and distribution systems account for most sulfur hexafluoride (SF_6) emissions. The electronics industry is the only source of nitrogen trifluoride (NF_3) emissions.

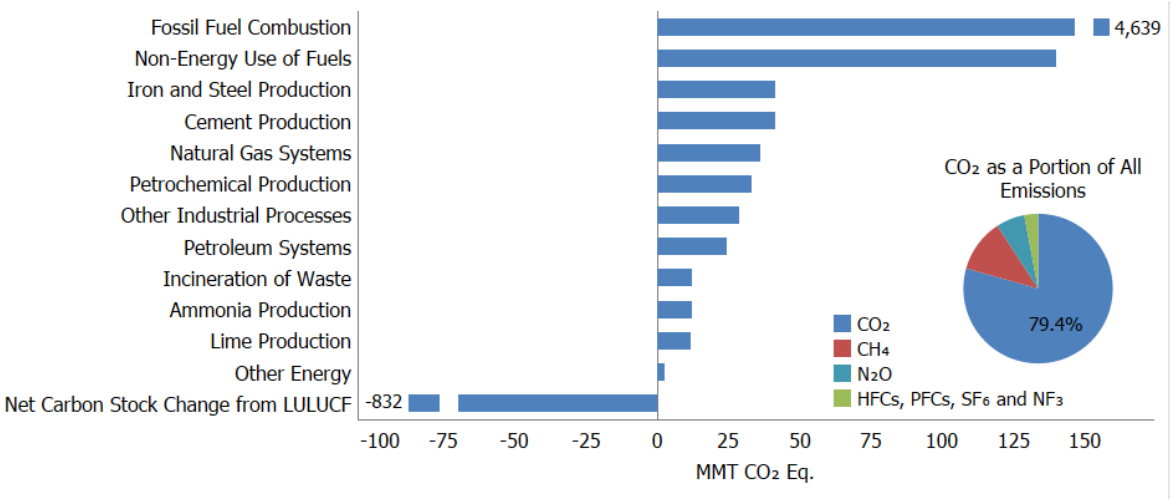
Figure ES-3: 2021 Total Gross U.S. Greenhouse Gas Emissions by Gas (Percentages based on MMT CO_2 Eq.)

Note: Emissions and removals from Land Use, Land-Use Change, and Forestry are excluded from figure above.

From 1990 to 2021, total emissions of CO_2 decreased by 88.7 MMT CO_2 Eq. (1.7 percent), total emissions of CH_4 decreased by 141.2 MMT CO_2 Eq. (16.3 percent), and emissions of N_2O decreased by 13.0 MMT CO_2 Eq. (3.2 percent). During the same period, emissions of fluorinated greenhouse gases including HFCs, PFCs, SF_6, and NF_3 rose by 95.9 MMT CO_2 Eq. (104.8 percent). From 1990 to 2021, emissions of HFCs increased by 136.1 MMT CO_2 Eq. (348.6 percent) and NF_3 emissions increased by 0.6 MMT CO_2 Eq. (1,318.9 percent), while emissions of PFCs decreased by 18.3 MMT CO_2 Eq. (83.8 percent) and SF_6 emissions decreased by 22.5 MMT CO_2 Eq. (73.7 percent). Despite being emitted in smaller quantities relative to the other principal greenhouse gases, emissions of HFCs, PFCs, SF_6 and NF_3 are significant because many of these gases have extremely high global warming potentials and, in the cases of PFCs and SF_6, long atmospheric lifetimes. Conversely, U.S. greenhouse gas emissions were partly offset by carbon (C) sequestration in forests, trees in urban areas, agricultural soils, landfilled yard trimmings and food scraps, and coastal wetlands, which together offset 13.1 percent of gross total emissions in 2021 (as reflected in Figure ES-1). The following sections describe each gas's contribution to total U.S. greenhouse gas emissions in more detail.

Carbon Dioxide Emissions

The global carbon cycle is made up of large carbon flows and reservoirs. Billions of tons of carbon in the form of CO_2 are absorbed by oceans and living biomass (i.e., sinks) and are emitted to the atmosphere annually through natural processes (i.e., sources). When in equilibrium, global carbon fluxes among these various reservoirs are roughly balanced.[14]



Since the Industrial Revolution (i.e., about 1750), global atmospheric concentrations of CO_2 have risen 48.1 percent (IPCC 2013; NOAA/ESRL 2023a), principally due to the combustion of fossil fuels for energy. Globally, an estimated

[14] The term "flux" is used to describe the exchange of CO_2 to and from the atmosphere, with net flux being either positive or negative depending on the overall balance. Removal and long-term storage of CO_2 from the atmosphere is also referred to as "carbon sequestration."

33,000 MMT of CO_2 were added to the atmosphere through the combustion of fossil fuels in 2021, of which the United States accounted for approximately 14.1 percent.[15]

Overall CO_2 emissions have decreased 2 percent since 1990 and increased 7 percent since 2020, consistent with increases in fuel combustion as noted above. Within the United States, fossil fuel combustion accounted for 92.2 percent of CO_2 gross emissions in 2021. Nationally, the fossil fuel combustion transportation subsector was the largest emitter of CO_2 in 2021 followed by the electric power generation subsector. There are 27 additional sources of CO_2 emissions included in the Inventory (see Table 2-1). Although not illustrated in Table ES-4, changes in land use and forestry practices can also lead to net CO_2 emissions (e.g., through conversion of forest land to agricultural or urban use) or to a net sink for CO_2 (e.g., through net additions to forest biomass). See more on these emissions and removals in Table ES-4.

Figure ES-4: 2021 Sources of CO_2 Emissions

Note: Other Industrial Processes includes emissions from Aluminum Production, Carbide Production and Consumption, Carbon Dioxide Consumption, Ferroalloy Production, Glass Production, Lead Production, Magnesium Production, Other Process Uses of Carbonates, Phosphoric Acid Production, Substitution of Ozone Depleting Substances, Soda Ash Production, Titanium Dioxide Production, Urea Consumption for Non-Agricultural Purposes, and Zinc Production. Other Energy includes emissions from Abandoned Oil and Gas Wells and Coal Mining.

As the largest source of U.S. greenhouse gas emissions, CO_2 from fossil fuel combustion has accounted for an average of 74.8 percent of CO_2-equivalent total gross U.S. emissions across the time series. Between 1990 and 2021, CO_2 emissions from fossil fuel combustion decreased from 4,728.2 MMT CO_2 Eq. to 4,639.1 MMT CO_2 Eq., a 1.9 percent total decrease. Carbon dioxide emissions from fossil fuel combustion decreased by 1,108.2 MMT CO_2 Eq. from 2005 levels, a decrease of 19.3 percent. From 2020 to 2021, these emissions increased by 294.2 MMT CO_2 Eq. (6.8 percent).

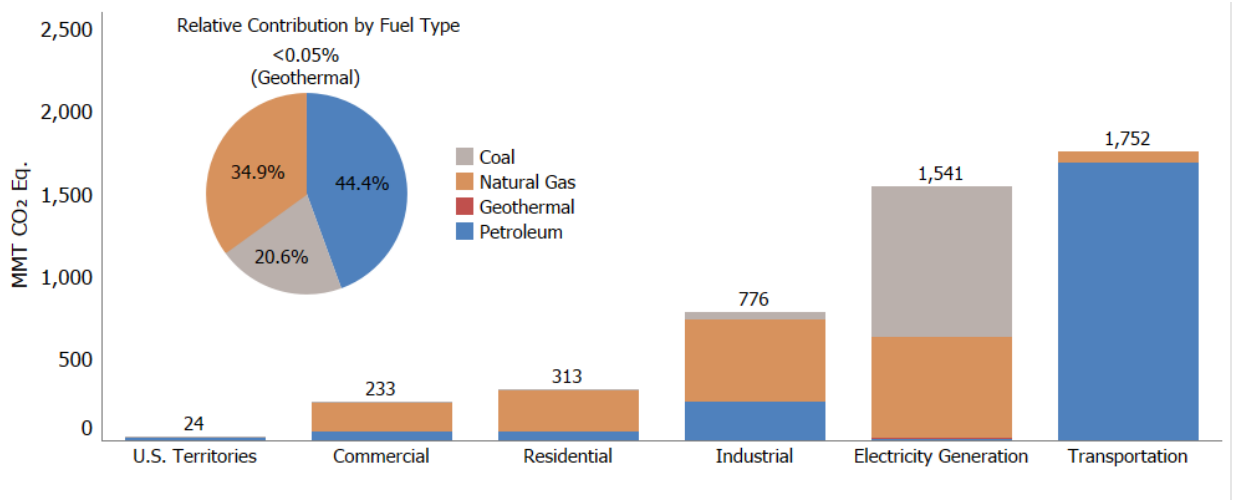
Historically, changes in emissions from fossil fuel combustion have been the driving factor affecting U.S. emission trends. Changes in CO_2 emissions from fossil fuel combustion are influenced by many long-term and short-term factors. Important drivers include: (1) changes in demand for energy; and (2) a general decline in the overall carbon intensity of fuels combusted for energy in recent years by non-transport sectors of the economy. Long-term factors affecting energy demand include population and economic trends, technological changes including energy efficiency, shifting energy fuel choices, and various policies at the national, state, and local level. In the short term, the overall consumption and mix of fossil fuels in the United States fluctuates primarily in response to changes in general economic conditions, overall energy prices, the relative price of different fuels, weather, and

[15] Global CO_2 emissions from fossil fuel combustion were taken from International Energy Agency *Global energy-related CO_2 emissions, 1990-2021 – Charts* Available at: https://www.iea.org/data-and-statistics/charts/global-energy-related-co2-emissions-1990-2021 (IEA 2022).

the availability of non-fossil alternatives. For example, between 2019 and 2021, changes in economic activity and travel due to the COVID-19 pandemic and the subsequent recovery have had significant impacts on energy use and fossil fuel combustion emissions.

The five major fuel-consuming economic sectors are transportation, electric power, industrial, residential, and commercial and are described below. Carbon dioxide emissions are produced by the electric power sector as fossil fuel is consumed to provide electricity to one of the other four sectors, or "end-use" sectors, see Figure ES-5. Note that this Figure reports emissions from U.S. Territories as their own end-use sector due to incomplete data for their individual end-use sectors. Fossil fuel combustion for electric power also includes emissions of less than 0.5 MMT CO_2 Eq. from geothermal-based generation.

Figure ES-5: 2021 CO_2 Emissions from Fossil Fuel Combustion by Sector and Fuel Type



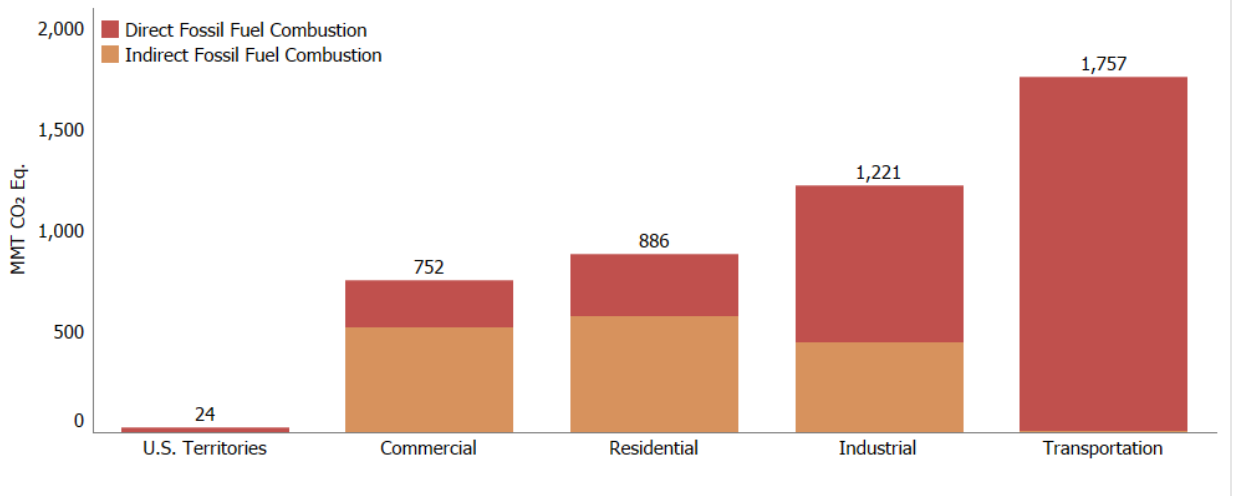


Table ES-6 summarizes CO_2 emissions from fossil fuel combustion by end-use sector including electric power emissions. For Figure ES-6, electric power emissions have been distributed to each end-use sector on the basis of each sector's share of aggregate electricity use (i.e., indirect fossil fuel combustion). This method of distributing emissions assumes that each end-use sector uses electricity that is generated from the national average mix of fuels according to their carbon intensity. Emissions from electric power are also addressed separately after the end-use sectors are discussed.

Figure ES-6: 2021 End-Use Sector Emissions of CO_2 from Fossil Fuel Combustion

Transportation End-Use Sector. Transportation activities accounted for 37.9 percent of U.S. CO_2 emissions from fossil fuel combustion in 2021, with the largest contributors being light-duty trucks (37.3 percent), followed by

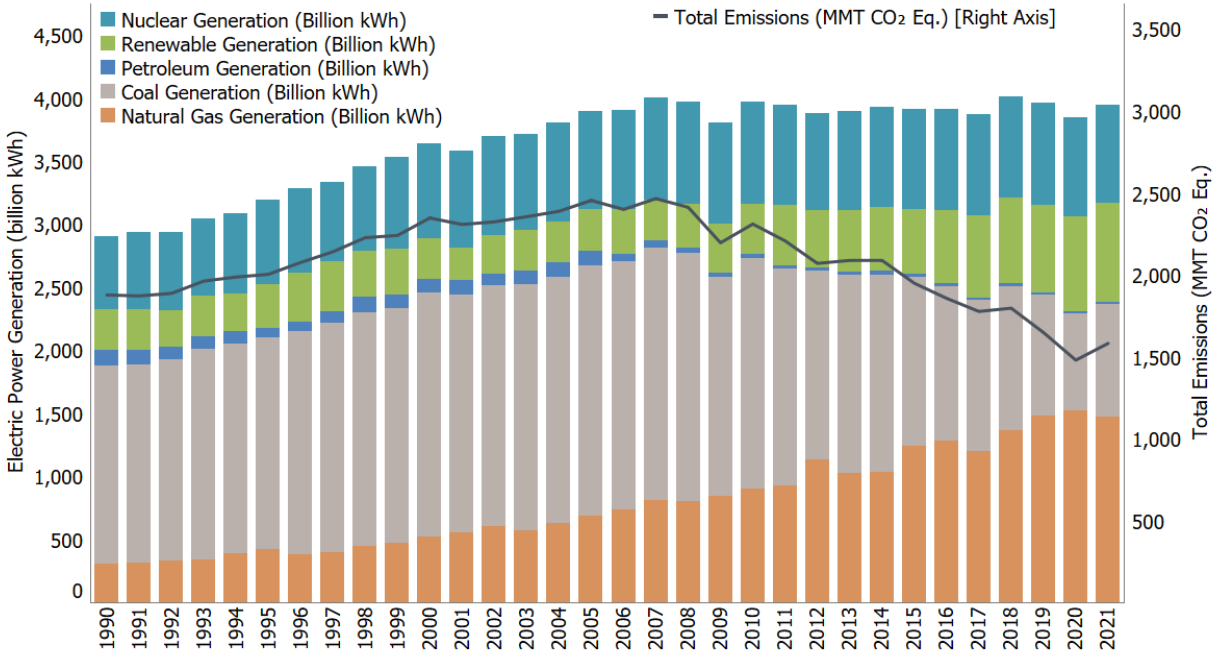
freight trucks (23.3 percent) and passenger vehicles (20.8 percent). Annex 3.2 presents the total emissions from all transportation and mobile sources, including CO_2, CH_4, N_2O, and HFCs.

In terms of the overall trend, from 1990 to 2021, total transportation CO_2 emissions increased due, in large part, to increased demand for travel which was a result of a confluence of factors including population growth, economic growth, urban sprawl, and low fuel prices during the beginning of this period. From 2020 to 2021, transportation CO_2 emissions, excluding emissions from international bunker fuels, increased 11.4 percent, largely reflective of a rebound in travel activity as COVID-19 pandemic restrictions were eased. While an increased demand for travel has led to generally increasing CO_2 emissions since 1990, improvements in average new vehicle fuel economy since 2005 have slowed the rate of increase of CO_2 emissions. In 2021, petroleum-based products supplied 94.5 percent of the energy consumed for transportation, primarily from gasoline consumption in automobiles and other highway vehicles (53.3 percent), diesel fuel for freight trucks (24.1 percent), jet fuel for aircraft (10.4 percent), and natural gas, residual fuel, aviation gasoline, and liquefied petroleum gases (6.8 percent). The remaining 5.5 percent is associated with renewable fuels (i.e., biofuels).

Industrial End-Use Sector. Industrial CO_2 emissions, resulting both directly from the combustion of fossil fuels and indirectly from the generation of electricity that is used by industry, accounted for 26.3 percent of CO_2 emissions from fossil fuel combustion in 2021. Approximately 63.5 percent of these emissions resulted from direct fossil fuel combustion to produce steam and/or heat for industrial processes. The remaining emissions resulted from the use of electricity for motors, electric furnaces, ovens, lighting, and other applications. Total direct and indirect emissions from the industrial sector have declined by 20.7 percent since 1990. This decline is due to structural changes in the U.S. economy (i.e., shifts from a manufacturing-based to a service-based economy), fuel switching, and efficiency improvements. From 2020 to 2021, total energy use in the industrial sector increased by 3.7 percent due to an increase in total industrial production and manufacturing output.

Residential and Commercial End-Use Sectors. The residential and commercial end-use sectors accounted for 19.1 and 16.2 percent, respectively, of CO_2 emissions from fossil fuel combustion in 2021 including indirect emissions from electricity. The residential and commercial sectors relied heavily on electricity for meeting energy demands, with 64.6 and 69.0 percent, respectively, of their emissions attributable to electricity use for lighting, heating, cooling, and operating appliances. The remaining emissions were due to the consumption of natural gas and petroleum for heating and cooking. Total direct and indirect emissions from the residential sector have decreased by 4.9 percent since 1990. Total direct and indirect emissions from the commercial sector have decreased by 1.9 percent since 1990. From 2020 to 2021, an increase in heating degree days (0.5 percent) increased energy demand for heating in the residential and commercial sectors, however, a 1.8 percent decrease in cooling degree days compared to 2020 reduced demand for air conditioning in the residential and commercial sectors. Combined, this resulted in a 1.5 percent increase in residential sector energy use. From 2020 to 2021 energy use in the commercial sector increased by 3.2 percent, due in part to the gradual recovery from the COVID-19 pandemic, which had reduced economic and manufacturing activity in 2020.

Electric Power. The United States relies on electricity to meet a significant portion of its energy demands. Electricity generators used 30.7 percent of U.S. energy from fossil fuels and emitted 33.2 percent of the CO_2 from fossil fuel combustion in 2021. The type of energy source used to generate electricity is the main factor influencing emissions.[16] The mix of fossil fuels used also impacts emissions. The electric power sector is the largest consumer of coal in the United States. The coal used by electricity generators accounted for 91.9 percent of all coal consumed for energy in the United States in 2021.[17] However, the amount of coal and the percent of total electricity generation from coal has been decreasing over time. Coal-fired electric generation (in kilowatt-hours



[16] In line with the reporting requirements for inventories submitted under the UNFCCC, CO_2 emissions from biomass combustion have been estimated separately from fossil fuel CO_2 emissions and are not included in the electricity sector totals and trends discussed in this section. Net carbon fluxes from changes in biogenic carbon reservoirs are accounted for in the estimates for Land Use, Land-Use Change, and Forestry.

[17] See Table 6.2 Coal Consumption by Sector of EIA (2022a).

[kWh]) decreased from 54.1 percent of generation in 1990 to 22.6 percent in 2021.[18] This corresponded with an increase in natural gas generation and non-fossil fuel renewable energy generation, largely from wind and solar energy. Natural gas generation (in kWh) represented 10.7 percent of electric power generation in 1990 and increased over the thirty-two-year period to represent 37.3 percent of electric power generation in 2021. Wind and solar generation (in kWh) represented 0.1 percent of electric power generation in 1990 and increased over the thirty-two-year period to represent 12.5 percent of electric power generation in 2021. The recovery from the COVID-19 pandemic led to an increase in electricity use of about 2.3 percent from 2020 to 2021. Between 2020 and 2021, coal electricity generation increased by 13.2 percent, natural gas generation decreased by 5.5 percent, and renewable energy generation increased by 1.7 percent.

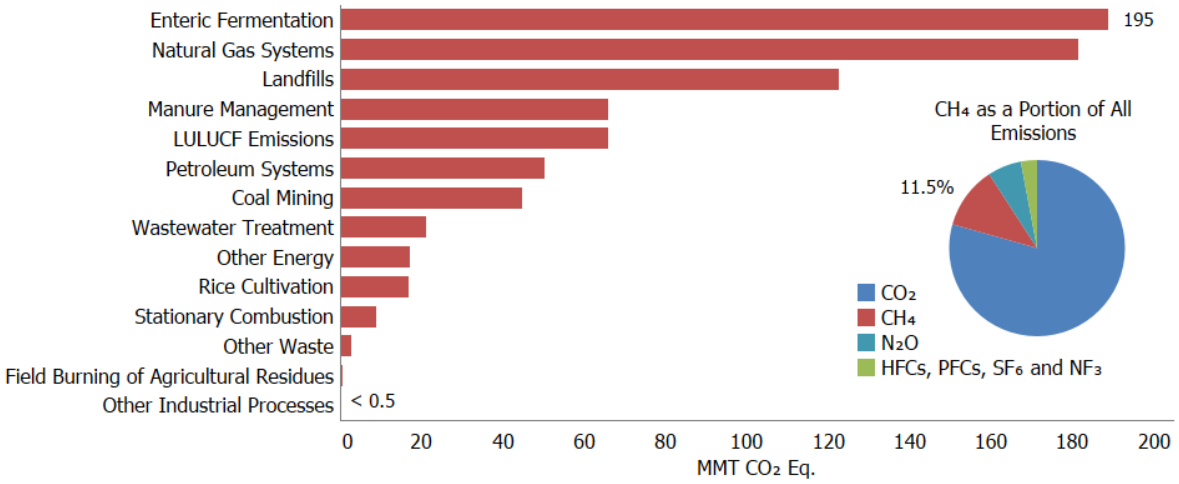
Across the time series, changes in electricity generation and the carbon intensity of fuels used for electric power have a significant impact on CO_2 emissions. While CO_2 emissions from fossil fuel combustion from the electric power sector have decreased by 15.3 percent since 1990, the carbon intensity of the electric power sector, in terms of CO_2 Eq. per QBtu input, has significantly decreased during that same timeframe by 24.9 percent. This decoupling of the level of electric power generation and the resulting CO_2 emissions is shown in Figure ES-7.

Figure ES-7: Electric Power Generation and Emissions

Other significant CO_2 trends included the following:

- Carbon dioxide emissions from natural gas and petroleum systems were 36.2 and 24.7 MMT CO_2 Eq., respectively, and combined accounted for 1.2 percent of CO_2 emissions and 1.0 percent of total gross emissions in 2021. These emissions increased by 19.1 MMT CO_2 Eq. (45.8 percent) from 1990 to 2021. This increase is due primarily to increases in the production segment, where flaring emissions from associated gas flaring, tanks, and miscellaneous production flaring have increased over time.
- Carbon dioxide emissions from iron and steel production and metallurgical coke production were 41.7 MMT CO_2 Eq. in 2021 and accounted for 0.8 percent of CO_2 and total gross emissions. Emissions have

[18] Values represent electricity *net* generation from the electric power sector. See Table 7.2b Electricity Net Generation: Electric Power Sector of EIA (2022a).



decreased by 63.1 MMT CO_2 Eq. (60.2 percent) from 1990 through 2021. This decrease is primarily due to restructuring of the industry, technological improvements, and increased scrap steel utilization.

- Total C stock change (i.e., net CO_2 removals) in the LULUCF sector decreased by 11.4 percent between 1990 and 2021. This decrease was primarily due to a decrease in the rate of net C accumulation in forest C stocks and Cropland Remaining Cropland*, as* well as an increase in emissions from Land Converted to Settlements.

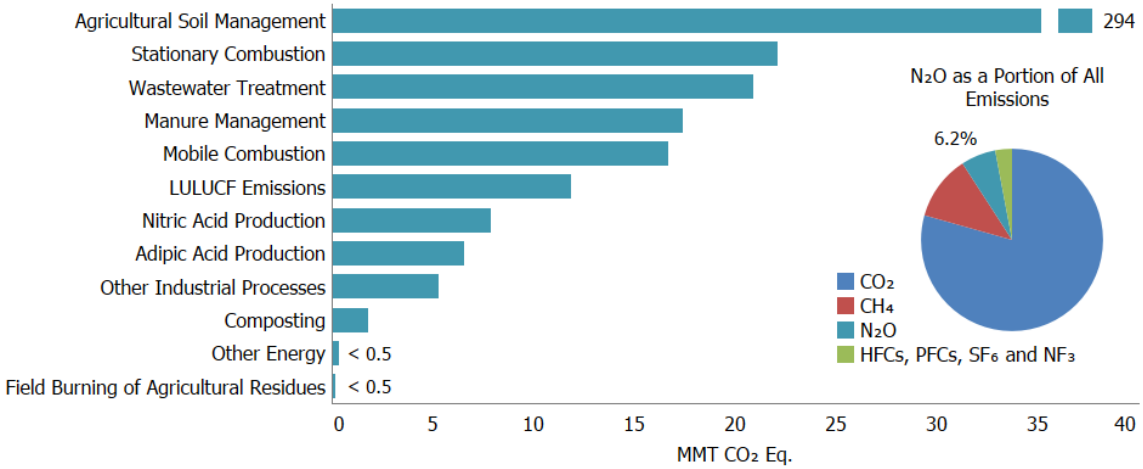
Methane Emissions

Methane (CH_4) is significantly more effective than CO_2 at trapping heat in the atmosphere–by a factor of 28 over a 100-year time frame based on the IPCC *Fifth Assessment Report* estimate (IPCC 2013). Over the last two hundred and fifty years, the concentration of CH_4 in the atmosphere increased by 170.8 percent (IPCC 2013; NOAA/ESRL 2023b). Within the United States, the main anthropogenic sources of CH_4 include enteric fermentation from domestic livestock, natural gas systems, landfills, domestic livestock manure management, coal mining, and petroleum systems (see Figure ES-8).

Figure ES-8: 2021 Sources of CH_4 Emissions

Note: Other Energy includes CH_4 emissions from Abandoned Oil and Gas Wells, Incineration of Waste, and Mobile Combustion. Other Waste includes CH_4 emissions from Anaerobic Digestion at Biogas Facilities and Composting. Other Industrial Processes includes CH_4 emissions from Carbide Production and Consumption, Ferroalloy Production, Iron and Steel Production, and Petrochemical Production. LULUCF emissions include the CH_4 reported for Peatlands Remaining Peatlands, Forest Fires, Drained Organic Soils, Grassland Fires, Coastal Wetlands Remaining Coastal Wetlands, Land Converted to Coastal Wetlands, Flooded Land Remaining Flooded Land, and Land Converted to Flooded Land.

Overall, CH_4 emissions in the United States in 2021, including LULUCF CH_4 emissions, accounted for 793.4 MMT CO_2 Eq., representing a decrease of 133.9 MMT CO_2 Eq. (14.4 percent) since 1990 and 14.3 MMT CO_2 Eq. (1.8 percent) since 2020. Significant trends for the largest sources of anthropogenic CH_4 emissions include the following:



- Enteric fermentation was the largest anthropogenic source of CH_4 emissions in the United States in 2021, accounting for 194.9 MMT CO_2 Eq. of CH_4 (26.4 percent of total CH_4 emissions and 3.1 percent of total gross emissions) and representing an increase of 11.9 MMT CO_2 Eq. (6.5 percent) since 1990. This increase in emissions from 1990 to 2021 generally follows the increasing trends in cattle populations.
- Natural gas systems were the second largest anthropogenic source category of CH_4 emissions in the United States in 2021, accounting for 181.4 MMT CO_2 Eq. of CH_4 (22.9 percent of total CH_4 emissions and 2.9 percent of total gross emissions). Emissions decreased by 33.7 MMT CO_2 Eq. (15.7 percent) since 1990 largely due to decreases in emissions from distribution, transmission, and storage.

- Landfills were the third largest anthropogenic source of CH_4 emissions in the United States in 2021, accounting for 122.6 MMT CO_2 Eq. (15.5 percent of total CH_4 emissions and 1.9 percent of total gross emissions) and representing a decrease of 75.1 MMT CO_2 Eq. (38.0 percent) since 1990, with small year-to-year increases. This downward trend in emissions coincided with increased landfill gas collection and control systems, and a reduction of decomposable materials (i.e., paper and paperboard, food scraps, and yard trimmings) discarded in MSW landfills over the time series.[19]

Nitrous Oxide Emissions

Nitrous oxide (N_2O) is produced by biological processes that occur in soil and water and by a variety of anthropogenic activities in the agricultural, energy, industrial, and waste management fields. While total N_2O emissions are much lower than CO_2 emissions, N_2O is 265 times more powerful than CO_2 at trapping heat in the atmosphere over a 100-year time frame (IPCC 2013). Since 1750, the global atmospheric concentration of N_2O has risen by 23.8 percent (IPCC 2013; NOAA/ESRL 2023c). The main anthropogenic activities producing N_2O in the United States are agricultural soil management, wastewater treatment, stationary fuel combustion, manure management, fuel combustion in motor vehicles, and nitric acid production (see Figure ES-9).

Figure ES-9: 2021 Sources of N_2O Emissions

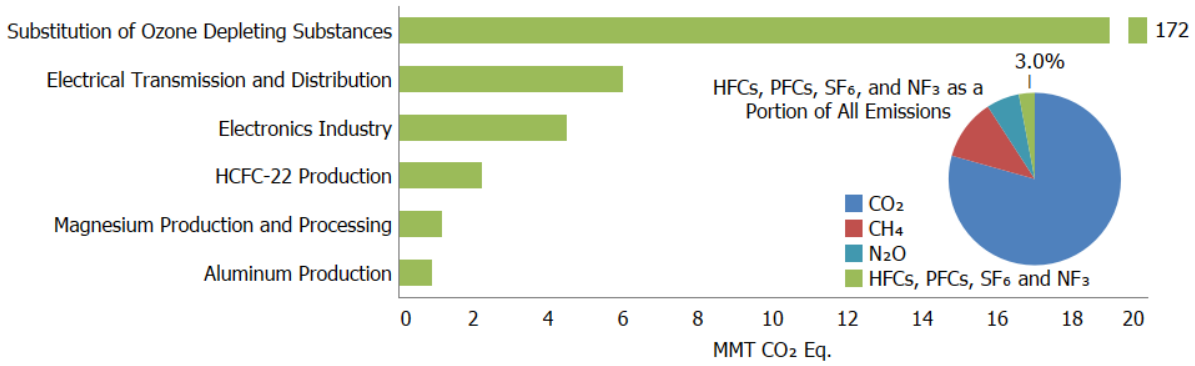
Note: Other Industrial Processes includes N_2O emissions from Caprolactam, Glyoxal, and Glyoxylic Acid Production; Electronics Industry; and Product Uses. Other Energy includes N_2O emissions from Petroleum Systems, Natural Gas Systems, and Incineration of Waste. LULUCF emissions include N_2O emissions reported for Peatlands Remaining Peatlands, Forest Fires, Drained Organic Soils, Grassland Fires, Coastal Wetlands Remaining Coastal Wetlands, Forest Soils, and Settlement Soils.

Overall, N_2O emissions in the United States in 2021, including LULUCF N_2O emissions, accounted for 405.1 MMT CO_2 Eq., representing an increase of 3.3 MMT CO_2 Eq. (0.8 percent) since 1990 and an increase of 5.3 MMT CO_2 Eq. (1.3 percent) since 2020. Significant trends for the largest sources of anthropogenic N_2O emissions include the following:

- Agricultural soils were the largest anthropogenic source of N_2O emissions in 2021, accounting for 294.0 MMT CO_2 Eq., 72.6 percent of N_2O emissions and 4.6 percent of total gross greenhouse gas emissions in the United States. These emissions increased by 6.1 MMT CO_2 Eq. (2.1 percent) from 1990 to 2021, but have fluctuated during that period due to annual variations in weather patterns, fertilizer use, and crop production.

[19] Carbon dioxide emissions from landfills are not included specifically in summing waste sector totals. Net carbon fluxes from changes in biogenic carbon reservoirs and decay of disposed wood products are accounted for in the estimates for LULUCF.

- Stationary combustion was the second largest source of anthropogenic N_2O emissions in 2021, accounting for 22.1 MMT CO_2 Eq. (5.5 percent of N_2O emissions) and 0.3 percent of total gross U.S. greenhouse gas emissions in 2021. Stationary combustion emissions peaked in 2007, and have steadily decreased since then.
- Wastewater treatment, both domestic and industrial, was the third largest anthropogenic source of N_2O emissions in 2021, accounting for 20.9 MMT CO_2 Eq., 5.2 percent of N_2O emissions and 0.3 percent of total gross greenhouse gas emissions in the United States in 2021. Emissions from wastewater treatment increased by 6.1 MMT CO_2 Eq. (41.6 percent) since 1990 as a result of growing U.S. population and protein consumption. Nitrous oxide emissions from industrial wastewater treatment sources fluctuated throughout the time series with production changes associated with the treatment of wastewater from the pulp and paper manufacturing, meat and poultry processing, fruit and vegetable processing, starch-based ethanol production, petroleum refining, and brewery industries.
- Nitrous oxide emissions from manure management accounted for 17.4 MMT CO_2 Eq., 4.3 percent of N_2O emissions and 0.3 percent of total gross greenhouse gas emissions in the United States in 2021. These emissions increased by 5.0 MMT CO_2 Eq. (40.5 percent) from 1990 to 2021. While the industry trend has been a shift toward liquid systems, driving down the emissions per unit of nitrogen excreted (dry manure handling systems have greater aerobic conditions that promote N_2O emissions), increases in specific animal populations have driven an increase in overall manure management N_2O emissions over the time series.
- Nitrous oxide emissions from mobile combustion, the fifth largest anthropogenic source of N_2O emissions in 2021, decreased by 21.7 MMT CO_2 Eq. (56.6 percent) from 1990 to 2021, primarily as a result of national vehicle emissions standards and emission control technologies for on-road vehicles.



HFC, PFC, SF_6, and NF_3 Emissions

Hydrofluorocarbons (HFCs) are synthetic chemicals that are used as alternatives to ozone depleting substances (ODS), which are being phased out under the Montreal Protocol and Clean Air Act Amendments of 1990. Hydrofluorocarbons do not deplete the stratospheric ozone layer and therefore have been used as alternatives under the *Montreal Protocol on Substances that Deplete the Ozone Layer*.

Perfluorocarbons (PFCs) are emitted from the production of electronics and aluminum and also (in smaller quantities) from their use as alternatives to ozone depleting substances. Sulfur hexafluoride (SF_6) is emitted from the manufacturing and use of electrical transmission and distribution equipment as well as the production of electronics and magnesium. NF_3 is emitted from electronics production. HFCs are also emitted during production of HCFC-22 and electronics (see Figure ES-10).

HFCs, PFCs, SF_6, and NF_3 are potent greenhouse gases. In addition to having very high global warming potentials, SF_6, NF_3, and PFCs have extremely long atmospheric lifetimes, resulting in their essentially irreversible accumulation in the atmosphere once emitted. Sulfur hexafluoride is the most potent greenhouse gas the IPCC has evaluated (IPCC 2021).

Figure ES-10: 2021 Sources of HFCs, PFCs, SF_6, and NF_3 Emissions

Some significant trends for the largest sources of U.S. HFC, PFC, SF_6, and NF_3 emissions include the following:

- Hydrofluorocarbon and perfluorocarbon emissions resulting from their use as substitutes for ODS (e.g., chlorofluorocarbons [CFCs]) are the largest share of fluorinated emissions (92.1 percent) in 2021 and have been consistently increasing, from small amounts in 1990 to 172.5 MMT CO_2 Eq. in 2021. This increase was in large part the result of efforts to phase out CFCs and other ODS in the United States.
- Sulfur hexafluoride emissions from electric power transmission and distribution systems decreased by 18.7 MMT CO_2 Eq. (75.7 percent) from 1990 to 2021. There are two factors contributing to this decrease: (1) a sharp increase in the price of SF_6 during the 1990s and (2) a growing awareness of the environmental impact of SF_6 emissions through programs such as EPA's SF_6 Emission Reduction Partnership for Electric Power Systems.
- HFC-23 emissions from HCFC-22 production decreased by 36.4 MMT CO_2 Eq. (94.2 percent) from 1990 to 2021. The decrease from 1990 emissions was caused primarily by a reduction in the HFC-23 emission rate (kg HFC-23 emitted/kg HCFC-22 produced). The emission rate was lowered by optimizing the production process and capturing much of the remaining HFC-23 for use or destruction.
- PFC emissions from aluminum production decreased by 18.4 MMT CO_2 Eq. (95.3 percent) from 1990 to 2021, due to both industry emission reduction efforts and lower domestic aluminum production.

ES.3 Overview of Sector Emissions and Trends

Figure ES-11 and Table ES-3 aggregate emissions and sinks by the sectors defined by the UNFCCC reporting guidelines and methodological framework in the IPCC Guidelines to promote comparability across countries. Over the thirty-two-year period of 1990 to 2021, total emissions from the Energy and Waste sectors decreased by 171.4 MMT CO_2 Eq. (3.2 percent) and 66.8 MMT CO_2 Eq. (28.3 percent) respectively. Emissions from the Industrial Processes and Product Use and Agriculture sectors grew by 41.0 MMT CO_2 Eq. (12.2 percent), and 50.0 MMT CO_2 Eq. (9.1 percent), respectively. Over the same period, the overall net flux from LULUCF (i.e., the net sum of all CH_4 and N_2O emissions to the atmosphere plus LULUCF net carbon stock changes in units of MMT CO_2 Eq.) decreased 126.7 MMT CO_2 Eq. (14 percent) and resulted in a removal of 754.2 MMT CO_2 Eq. in 2021.

Figure ES-11: U.S. Greenhouse Gas Emissions and Sinks by IPCC Sector

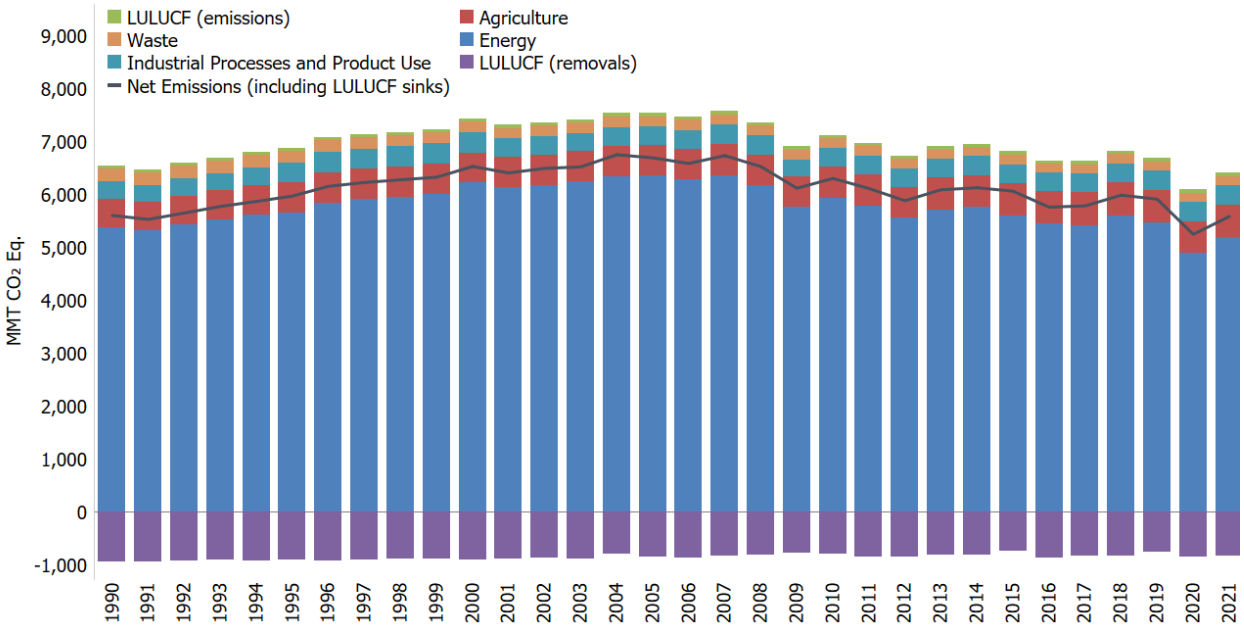


Table ES-3: Recent Trends in U.S. Greenhouse Gas Emissions and Sinks by IPCC Sector (MMT CO_2 Eq.)

IPCC Sector	1990	2005	2017	2018	2019	2020	2021
Energy	5,368.0	6,351.5	5,418.7	5,589.5	5,460.6	4,894.0	5,196.6
Industrial Processes and Product Use	335.4	356.1	359.1	362.2	366.8	363.2	376.4
Agriculture	548.0	577.7	613.1	629.5	614.5	597.3	598.1
Waste	236.0	192.1	170.9	173.7	176.0	171.5	169.2
Total Gross Emissions[a] (Sources)	**6,487.3**	**7,477.4**	**6,561.8**	**6,754.8**	**6,617.9**	**6,026.0**	**6,340.2**

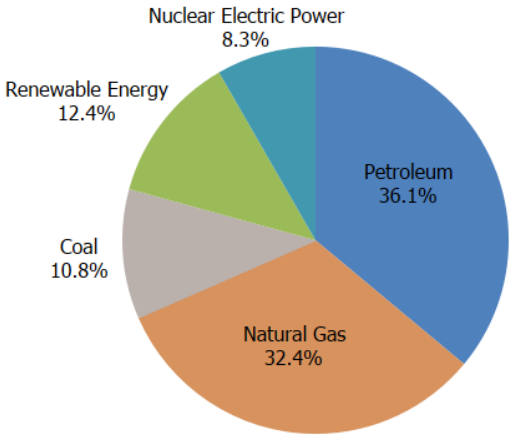
[a] Total emissions without LULUCF.

[b] The LULUCF Sector Net Total is the sum of all LULUCF CH_4 and N_2O emissions to the atmosphere plus LULUCF net carbon stock changes in units of MMT CO_2 Eq.

[c] Net emissions with LULUCF.



Notes: Total emissions presented without LULUCF. Net emissions are presented with LULUCF. Totals may not sum due to independent rounding. Parentheses indicate negative values or sequestration.

Energy

The Energy chapter contains emissions of all greenhouse gases resulting from stationary and mobile energy activities including fuel combustion and fugitive fuel emissions, and the use of fossil fuels for non-energy purposes. Energy-related activities, primarily fossil fuel combustion, accounted for the vast majority of U.S. CO_2 emissions for the period of 1990 through 2021. Energy-related activities are also responsible for CH_4 and N_2O emissions (41.6 percent and 10.0 percent of total U.S. emissions of each gas, respectively). Overall, emission sources in the Energy chapter account for a combined 82.0 percent of total gross U.S. greenhouse gas emissions in 2021. Emissions from energy increased by 302.6 MMT CO_2 Eq. (6.2 percent) since 2020, but they have decreased by 171.4 MMT CO_2 Eq. (3.2 percent) since 1990.

In 2021, 79.3 percent of the energy used in the United States (on a Btu basis) was produced through the combustion of fossil fuels. The remaining 20.7 percent came from other energy sources, such as hydropower, biomass, nuclear, wind, and solar energy (see Figure ES-12).

Figure ES-12: 2021 U.S. Energy Consumption by Energy Source (Percent)

Industrial Processes and Product Use

The Industrial Processes and Product Use (IPPU) chapter contains greenhouse gas emissions generated and emitted as the byproducts of non-energy-related industrial processes, which involve the chemical or physical transformation of raw materials and can release waste gases such as CO_2, CH_4, N_2O, and fluorinated gases (e.g., HFC-23). These processes include iron and steel production and metallurgical coke production, cement production, petrochemical production, ammonia production, lime production, other process uses of carbonates (e.g., flux stone, flue gas desulfurization, and soda ash consumption not associated with glass manufacturing), nitric acid production, adipic acid production, urea consumption for non-agricultural purposes, aluminum production, HCFC-22 production, glass production, soda ash production, ferroalloy production, titanium dioxide production, caprolactam production, zinc production, phosphoric acid production, lead production, and silicon carbide production and consumption. Most of these industries also emit CO_2 from fossil fuel combustion which, in line with IPCC sectoral definitions, is included in the Energy sector.

This chapter also contains emissions resulting from the release of HFCs, PFCs, SF_6, and NF_3 and other man-made compounds used in industrial manufacturing processes and by end-consumers (e.g., residential and mobile air conditioning). These industries include electronics manufacturing, electric power transmission and distribution, and magnesium metal production and processing. In addition, N_2O is used in and emitted by electronics industry and anesthetic and aerosol applications, and CO_2 is consumed and emitted through various end-use applications. In 2021, emissions resulting from use of the substitution of ODS (e.g., chlorofluorocarbons [CFCs]) by end-consumers was the largest source of IPPU emissions and accounted for 172.5 MMT CO_2 Eq, or 45.8 percent of total IPPU emissions.

IPPU activities are responsible for 3.4, 0.1, and 5.0 percent of total U.S. CO_2, CH_4, and N_2O emissions respectively as well as for all U.S. emissions of fluorinated gases including HFCs, PFCs, SF_6 and NF_3. Overall, emission sources in the IPPU chapter accounted for 5.9 percent of U.S. greenhouse gas emissions in 2021. IPPU emissions increased by 13.2 MMT CO_2 Eq. (3.6 percent) since 2020 and by 41 MMT CO_2 Eq. (12.2 percent) since 1990, mostly due to increased use of ODS substitutes (e.g., HFCs).

Agriculture

The Agriculture chapter contains information on anthropogenic emissions from agricultural activities (except fuel combustion, which is addressed in the Energy chapter, and some agricultural CO_2, CH_4, and N_2O fluxes, which are addressed in the Land Use, Land-Use Change, and Forestry chapter).

Agricultural activities contribute directly to emissions of greenhouse gases through a variety of processes, including the following sources: agricultural soil management, enteric fermentation in domestic livestock, livestock manure management, rice cultivation, urea fertilization, liming, and field burning of agricultural residues.

In 2021, agricultural activities were responsible for emissions of 598.1 MMT CO_2 Eq., or 9.4 percent of total gross U.S. greenhouse gas emissions. Agriculture sector emissions increased slightly (0.8 MMT CO_2 Eq. or 0.1 percent) since 2020 and have increased by 50 MMT CO_2 Eq. (9.1 percent) since 1990, mostly from trends in enteric fermentation and manure management. Methane, N_2O, and CO_2 are greenhouse gases emitted by agricultural activities. Methane emissions from enteric fermentation and manure management represented 35.9 percent of total CH_4 emissions from anthropogenic activities in 2021. Agricultural soil management activities, such as application of synthetic and organic fertilizers, deposition of livestock manure, and growing N-fixing plants, were the largest contributors to U.S. N_2O emissions in 2021, accounting for 74.8 percent of total N_2O emissions. Carbon dioxide emissions from the application of crushed limestone and dolomite (i.e., soil liming) and urea fertilization represented 0.2 percent of total CO_2 emissions from anthropogenic activities.

Land Use, Land-Use Change, and Forestry

The LULUCF chapter contains emissions and removals of CO_2 and emissions of CH_4 and N_2O from managed lands in the United States. Consistent with the *2006 IPCC Guidelines*, emissions and removals from managed lands are considered to be anthropogenic, while emissions and removals from unmanaged lands are considered to be natural.[20] The share of managed land in the U.S. is approximately 95 percent of total land included in the Inventory.[21] More information on the definition of managed land used in the Inventory is provided in Chapter 6.

Overall, the Inventory results show that managed land is a net sink for CO_2 (C sequestration). The primary drivers of fluxes on managed lands include forest management practices, tree planting in urban areas, the management of agricultural soils, lands remaining and lands converted to reservoirs and other constructed waterbodies, landfilling of yard trimmings and food scraps, and activities that cause changes in C stocks in coastal wetlands. The main drivers for forest C sequestration include forest growth and increasing forest area (i.e., afforestation), as well as a net accumulation of C stocks in harvested wood pools. The net sequestration in Settlements Remaining Settlements, which occurs predominantly from urban forests (i.e., Settlement Trees) and landfilled yard trimmings and food scraps, is a result of net tree growth and increased urban forest area, as well as long-term accumulation of yard trimmings and food scraps carbon in landfills.

The LULUCF sector in 2021 resulted in a net increase in C stocks (i.e., net CO_2 removals) of 832.0 MMT CO_2 Eq.[22] The removals of C offset 13.1 percent of total gross greenhouse gas emissions in 2021. Emissions of CH_4 and N_2O from LULUCF activities in 2021 were 77.8 MMT CO_2 Eq. and represent 1.4 percent of net greenhouse gas emissions.[23] Carbon dioxide removals from C stock changes are presented in Table ES-4 along with CH_4 and N_2O emissions for LULUCF source categories.

[20] See http://www.ipcc-nggip.iges.or.jp/public/2006gl/pdf/4_Volume4/V4_01_Ch1_Introduction.pdf.

[21] The current land representation does not include land in U.S. Territories, but there are planned improvements to include these regions in future Inventories. U.S. Territories represent approximately 0.1 percent of the total land base for the United States. See Box 6-2 in Chapter 6 of this report.

[22] LULUCF Carbon Stock Change is the net C stock change from the following categories: Forest Land Remaining Forest Land, Land Converted to Forest Land, Cropland Remaining Cropland, Land Converted to Cropland, Grassland Remaining Grassland, Land Converted to Grassland, Wetlands Remaining Wetlands, Land Converted to Wetlands, Settlements Remaining Settlements, and Land Converted to Settlements.

[23] LULUCF emissions include the CH_4 and N_2O emissions reported for Peatlands Remaining Peatlands, Forest Fires, Drained Organic Soils, Grassland Fires, and Coastal Wetlands Remaining Coastal Wetlands; CH_4 emissions from Land Converted to Coastal Wetlands; and N_2O emissions from forest soils and settlement soils.

Between 1990 and 2021, total C sequestration in the LULUCF sector decreased by 11.4 percent, primarily due to a decrease in the rate of net C accumulation in forests and Cropland Remaining Cropland, as well as an increase in CO_2 emissions from Land Converted to Settlements. The overall net flux from LULUCF (i.e., net sum of all CH_4 and N_2O emissions to the atmosphere plus LULUCF net carbon stock changes in units of MMT CO_2 eq.) resulted in a removal of 754.2 MMT CO_2 Eq. in 2021.

Flooded lands were the largest source of CH_4 emissions from the LULUCF sector in 2021, totaling 45.4 MMT CO_2 Eq. (1,623 kt of CH_4). Forest fires were the second largest source and resulted in CH_4 emissions of 15.5 MMT CO_2 Eq. (554 kt of CH_4), followed by Coastal Wetlands Remaining Coastal Wetlands with CH_4 emissions of 4.3 MMT CO_2 Eq. (154 kt of CH_4).

Forest fires were the largest source of N_2O emissions from the LULUCF sector in 2021, totaling 8.9 MMT CO_2 Eq. (34 kt of N_2O). Nitrous oxide emissions from fertilizer application to settlement soils in 2021 totaled 2.1 MMT CO_2 Eq. (8 kt of N_2O).

Table ES-4: U.S. Greenhouse Gas Emissions and Removals (Net Flux) from Land Use, Land-Use Change, and Forestry (MMT CO_2 Eq.)

Land-Use Category	1990	2005	2017	2018	2019	2020	2021
Forest Land Remaining Forest Land[a]	(815.8)	(695.4)	(695.2)	(692.9)	(638.1)	(684.0)	(670.5)

Land Converted to Grassland[c]	(6.7)	(40.1)	(24.5)	(24.2)	(23.3)	(25.9)	(24.7)
Wetlands Remaining Wetlands[e]	41.5	43.1	41.8	41.8	41.8	41.8	41.8
Land Converted to Wetlands[e]	3.3	1.4	0.8	0.8	0.8	0.6	0.6
Settlements Remaining Settlements[f]	(107.8)	(113.9)	(125.6)	(125.0)	(124.5)	(131.6)	(132.5)
Land Converted to Settlements[c]	62.5	85.0	80.9	81.0	81.1	81.0	81.0
LULUCF Carbon Stock Change[g]	**(938.9)**	**(853.5)**	**(842.5)**	**(829.5)**	**(768.2)**	**(852.5)**	**(832.0)**
LULUCF Emissions[h]	**57.9**	**72.4**	**68.3**	**64.4**	**64.2**	**76.4**	**77.8**
CH_4	53.5	61.3	60.1	57.3	56.9	65.4	66.0
N_2O	4.4	11.1	8.3	7.0	7.3	11.0	11.8
LULUCF Sector Net Total[i]	**(881.0)**	**(781.1)**	**(774.2)**	**(765.1)**	**(704.0)**	**(776.2)**	**(754.2)**

[a] Includes the net changes to carbon stocks stored in all forest ecosystem pools and harvested wood products, emissions from fires on both Forest Land Remaining Forest Land and Land Converted to Forest Land, emissions from N fertilizer additions on both Forest Land Remaining Forest Land and Land Converted to Forest Land, and CH_4 and N_2O emissions from drained organic soils on both Forest Land Remaining Forest Land and Land Converted to Forest Land.

[b] Includes the net changes to carbon stocks stored in all forest ecosystem pools.

[c] Includes changes in mineral and organic soil carbon stocks for all land use conversions to cropland, grassland, and settlements, respectively. Also includes aboveground/belowground biomass, dead wood, and litter carbon stock changes for conversion of forest land to cropland, grassland, and settlements, respectively.

[d] Estimates include CH_4 and N_2O emissions from fires on both Grassland Remaining Grassland and Land Converted to Grassland.

[e] Estimates include CH_4 emissions from Flooded Land Remaining Flooded Land and Land Converted to Flooded Land.

[f] Estimates include N_2O emissions from N fertilizer additions on both Settlements Remaining Settlements and Land Converted to Settlements because it is not possible to separate the activity data at this time.

[g] LULUCF Carbon Stock Change includes any C stock gains and losses from all land use and land use conversion categories.

[h] LULUCF emissions subtotal includes the CH_4 and N_2O emissions reported for Peatlands Remaining Peatlands, Forest Fires, Drained Organic Soils, Grassland Fires, and Coastal Wetlands Remaining Coastal Wetlands; CH_4 emissions from Land Converted to Coastal Wetlands, Flooded Land Remaining Flooded Land, and Land Converted to Flooded Land; and N_2O emissions from forest soils and settlement soils. Emissions values are included in land-use category rows.

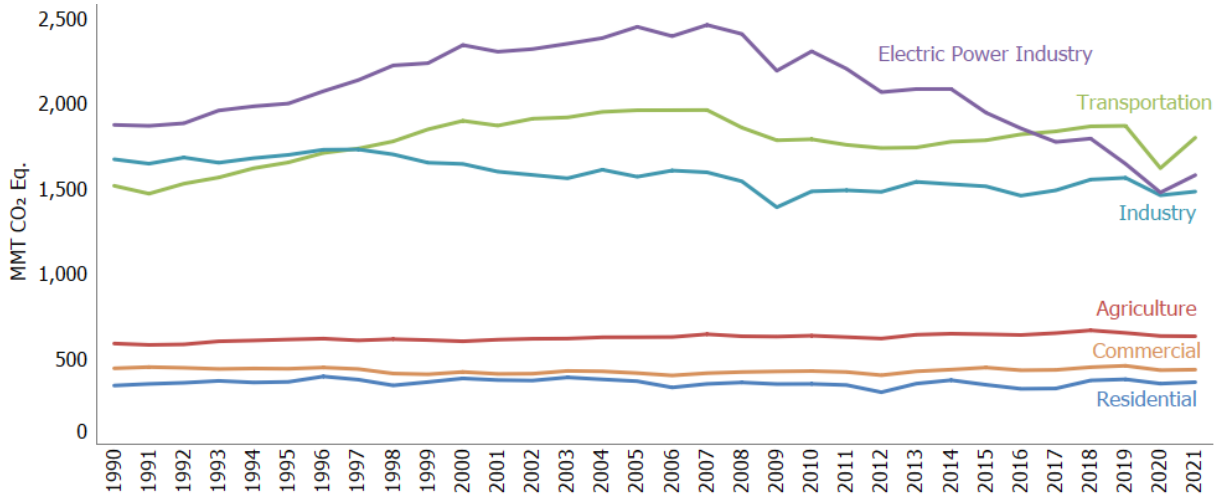
[i] The LULUCF Sector Net Total is the net sum of all LULUCF CH_4 and N_2O emissions to the atmosphere plus LULUCF net carbon stock changes in units of MMT CO_2 Eq.

Notes: Totals may not sum due to independent rounding. Parentheses indicate net sequestration.

Waste

The Waste chapter contains emissions from waste management activities (except the incineration of waste, which is addressed in the Energy chapter). Landfills were the largest source of anthropogenic greenhouse gas emissions from waste management activities, generating 122.6 MMT CO_2 Eq. and accounting for 72.5 percent of total greenhouse gas emissions from waste management activities, and 16.9 percent of total U.S. CH_4 emissions.[24] Additionally, wastewater treatment generated emissions of 42.0 MMT CO_2 Eq. and accounted for 24.8 percent of total Waste sector greenhouse gas emissions, 2.9 percent of U.S. CH_4 emissions, and 5.3 percent of U.S. N_2O emissions in 2021. Emissions of CH_4 and N_2O from composting are also accounted for in this chapter, generating emissions of 2.6 MMT CO_2 Eq., and 1.8 MMT CO_2 Eq., respectively. Anaerobic digestion at biogas facilities generated CH_4 emissions of 0.2 MMT CO_2 Eq., accounting for 0.1 percent of emissions from the waste sector. Overall, emission sources accounted for in the Waste chapter generated 169.2 MMT CO_2 Eq., or 2.7 percent of total gross U.S. greenhouse gas emissions in 2021. Waste sector emissions decreased by 2.4 MMT CO_2 Eq. (1.4 percent) since 2020 and by 66.8 MMT CO_2 Eq. (28.3 percent) since 1990.

ES.4 Other Information



Emissions by Economic Sector

Throughout the *Inventory of U.S. Greenhouse Gas Emissions and Sinks* report, emission estimates are grouped into five sectors (i.e., chapters) defined by the IPCC: Energy, IPPU, Agriculture, LULUCF, and Waste. It is also useful to characterize emissions according to commonly used economic sector categories: Residential, Commercial, Industry, Transportation, Electric Power, and Agriculture. Emissions from U.S. Territories are reported as their own end-use sector due to a lack of specific consumption data for the individual end-use sectors within U.S. Territories. For more information on trends in the Land Use, Land-Use Change, and Forestry sector, see Section ES.2 Recent Trends in U.S. Greenhouse Gas Emissions and Sinks.

Figure ES-13 shows the trend in emissions by economic sector from 1990 to 2021, and Table ES-5 summarizes emissions from each of these economic sectors.

[24] Landfills also store carbon, due to incomplete degradation of organic materials such as harvest wood products, yard trimmings, and food scraps, as described in the Land Use, Land-Use Change, and Forestry chapter of the Inventory report.

Figure ES-13: U.S. Greenhouse Gas Emissions Allocated to Economic Sectors

Note: Emissions and removals from Land Use, Land-Use Change, and Forestry are excluded from figure above. Excludes U.S. Territories.

Table ES-5: U.S. Greenhouse Gas Emissions Allocated to Economic Sectors (MMT CO_2 Eq.)

Economic Sectors	1990	2005	2017	2018	2019	2020	2021
Transportation	1,521.4	1,966.0	1,841.6	1,871.3	1,874.3	1,624.9	1,804.3
Electric Power Industry	1,879.7	2,456.9	1,779.2	1,799.1	1,650.5	1,481.8	1,584.1
Industry	1,677.3	1,574.4	1,494.5	1,558.0	1,568.2	1,465.4	1,487.3
Agriculture	592.9	630.2	654.2	670.6	655.4	637.2	635.8
Commercial	447.0	418.9	437.6	453.7	462.0	436.0	439.2
Residential	345.6	371.2	328.4	375.8	382.4	356.9	365.6
U.S. Territories	23.4	59.7	26.3	26.3	25.1	23.6	24.1
Total Gross Emissions (Sources)	**6,487.3**	**7,477.4**	**6,561.8**	**6,754.8**	**6,617.9**	**6,026.0**	**6,340.2**
LULUCF Sector Net Total[a]	(881.0)	(781.1)	(774.2)	(765.1)	(704.0)	(776.2)	(754.2)
Net Emissions (Sources and Sinks)	**5,606.4**	**6,696.3**	**5,787.6**	**5,989.7**	**5,913.9**	**5,249.8**	**5,586.0**

[a] The LULUCF Sector Net Total is the net sum of all LULUCF CH_4 and N_2O emissions to the atmosphere plus LULUCF net carbon stock changes.

Notes: Total (gross) emissions are presented without LULUCF. Total net emissions are presented with LULUCF. Totals may not sum due to independent rounding. Parentheses indicate negative values or sequestration.

Using this categorization, emissions from transportation activities accounted for the largest portion (28.5 percent) of total gross U.S. greenhouse gas emissions in 2021. Electric power accounted for the second largest portion (25.0 percent) of U.S. greenhouse gas emissions in 2021, while emissions from industry accounted for the third largest portion (23.5 percent). Emissions from industry have in general declined over the past decade, due to a number of factors, including structural changes in the U.S. economy (i.e., shifts from a manufacturing-based to a service-based economy), fuel switching, and energy efficiency improvements.

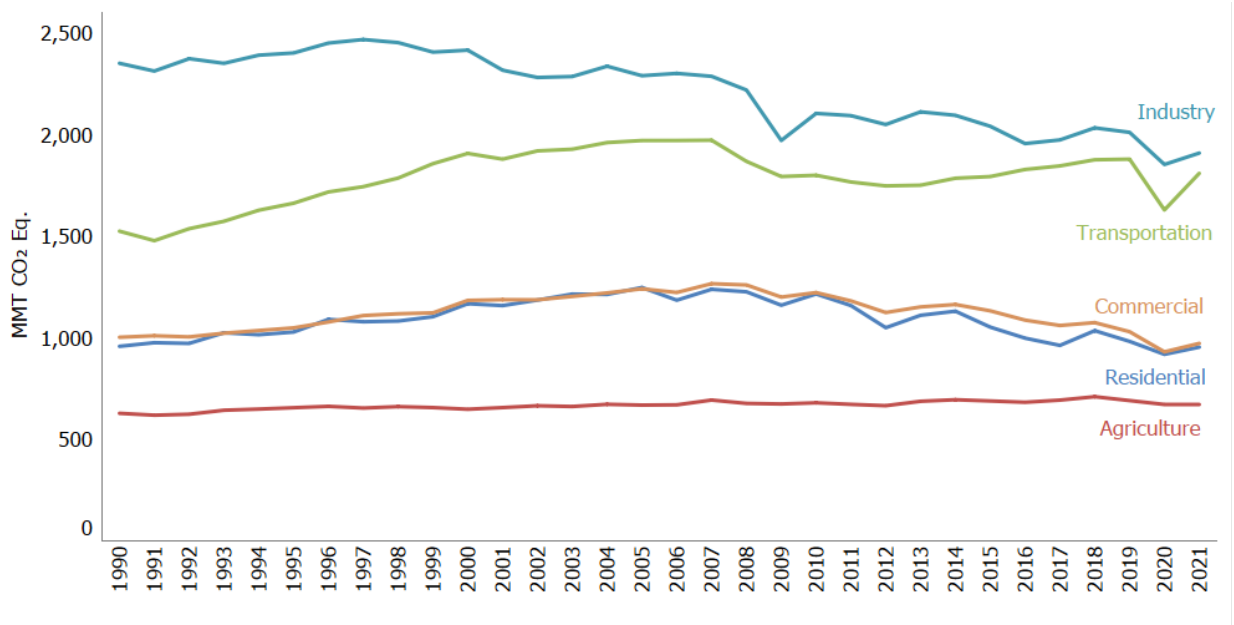
The remaining 23.1 percent of U.S. greenhouse gas emissions were contributed by, in order of magnitude, the agriculture, commercial, and residential sectors, plus emissions from U.S. Territories. Activities related to agriculture accounted for 10.0 percent of U.S. emissions; unlike other economic sectors, agricultural sector emissions were dominated by N_2O emissions from agricultural soil management and CH_4 emissions from enteric fermentation. An increasing amount of carbon is stored in agricultural soils each year, but this CO_2 sequestration is assigned to the LULUCF sector rather than the agriculture economic sector. The commercial and residential sectors accounted for 6.9 percent and 5.8 percent of emissions, respectively, and U.S. Territories accounted for 0.4

percent of emissions; emissions from these sectors primarily consisted of CO_2 emissions from fossil fuel combustion. Carbon dioxide was also emitted and sequestered by a variety of activities related to forest management practices, tree planting in urban areas, the management of agricultural soils, landfilling of yard trimmings, and changes in C stocks in coastal wetlands.

Electricity is ultimately used in the economic sectors described above. Table ES-6 presents greenhouse gas emissions from economic sectors with emissions related to electric power distributed into end-use categories (i.e., emissions from electric power generation are allocated to the economic sectors in which the electricity is used). To distribute electricity emissions among end-use sectors, emissions from the source categories assigned to electric power were allocated to the residential, commercial, industry, transportation, and agriculture economic sectors according to retail sales of electricity for each end-use sector (EIA 2022).[25] These source categories include CO_2 from fossil fuel combustion and the use of limestone and dolomite for flue gas desulfurization, CO_2 and N_2O from incineration of waste, CH_4 and N_2O from stationary sources, and SF_6 from electrical transmission and distribution systems.

When emissions from electricity use are distributed among these end-use sectors, industrial activities and transportation account for the largest shares of U.S. greenhouse gas emissions (30.1 percent and 28.5 percent, respectively) in 2021. The commercial and residential sectors contributed the next largest shares of total gross U.S. greenhouse gas emissions in 2021 (15.3 and 15.0 percent, respectively). Emissions from the commercial and residential sectors increase substantially when emissions from electricity use are included, due to their relatively large share of electricity use for energy (e.g., lighting, cooling, appliances). Figure ES-14 shows the trend in these emissions by sector from 1990 to 2021.

Table ES-6: U.S. Greenhouse Gas Emissions with Electricity-Related Emissions Distributed by Economic Sector (MMT CO_2 Eq.)



Economic Sectors	1990	2005	2017	2018	2019	2020	2021
Industry	2,351.1	2,289.9	1,973.9	2,033.2	2,011.2	1,852.9	1,909.2
Transportation	1,524.6	1,970.9	1,846.0	1,876.2	1,879.2	1,629.2	1,809.5
Commercial	1,002.4	1,241.0	1,060.4	1,074.5	1,029.7	930.5	972.2
Residential	957.8	1,247.5	962.3	1,034.9	982.0	918.3	953.8
Agriculture	628.0	668.5	693.0	709.8	690.7	671.5	671.5
U.S. Territories	23.4	59.7	26.3	26.3	25.1	23.6	24.1
Total Gross Emissions (Sources)	**6,487.3**	**7,477.4**	**6,561.8**	**6,754.8**	**6,617.9**	**6,026.0**	**6,340.2**
LULUCF Sector Net Total[a]	(881.0)	(781.1)	(774.2)	(765.1)	(704.0)	(776.2)	(754.2)
Net Emissions (Sources and Sinks)	**5,606.4**	**6,696.3**	**5,787.6**	**5,989.7**	**5,913.9**	**5,249.8**	**5,586.0**

[a] The LULUCF Sector Net Total is the net sum of all LULUCF CH_4 and N_2O emissions to the atmosphere plus LULUCF net carbon stock changes.

Notes: Emissions from electric power are allocated based on aggregate electricity use in each end-use sector. Totals may not sum due to independent rounding. Parentheses indicate negative values or sequestration.

[25] U.S. Territories consumption data that are obtained from EIA are only available at the aggregate level and cannot be broken out by end-use sector. The distribution of emissions to each end-use sector for the 50 states does not apply to territories data.

Figure ES-14: U.S. Greenhouse Gas Emissions with Electricity-Related Emissions Distributed to Economic Sectors

Note: Emissions and removals from Land Use, Land-Use Change, and Forestry are excluded from figure above. Excludes U.S. Territories.

Box ES-2: Trends in Various U.S. Greenhouse Gas Emissions-Related Data

Total (gross) greenhouse gas emissions can be compared to other economic and social indices to highlight changes over time. These comparisons include: (1) emissions per unit of aggregate energy use, because energy-related activities are the largest sources of emissions; (2) emissions per unit of fossil fuel consumption, because almost all energy-related emissions involve the combustion of fossil fuels; (3) emissions per unit of total gross domestic product as a measure of national economic activity; and (4) emissions per capita.

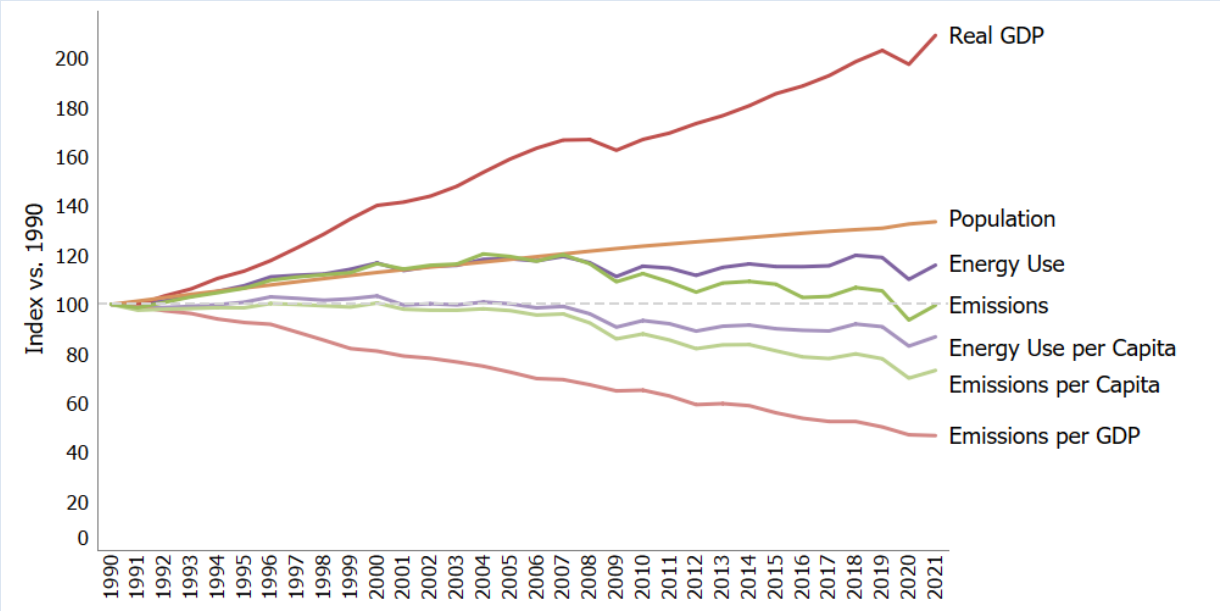


Table ES-7 provides data on various statistics related to U.S. greenhouse gas emissions normalized to 1990 as a baseline year. These values represent the relative change in each statistic since 1990. Greenhouse gas emissions in the United States have declined at an average annual rate of 0.02 percent since 1990, although changes from year to year have been significantly larger. This growth rate is slightly slower than that for total energy use and fossil fuel consumption, and overall gross domestic product (GDP), and national population (see Figure ES-15). The direction of these trends started to change after 2005, when greenhouse gas emissions, total energy use, and fossil fuel consumption began to peak. Greenhouse gas emissions in the United States have decreased at an average annual rate of 0.9 percent since 2005. Fossil fuel consumption has decreased at a slower rate than emissions since 2005, while total energy use, GDP, and national population, generally, continued to increase noting 2020 was impacted by COVID-19 pandemic.

Table ES-7: Recent Trends in Various U.S. Data (Index 1990 = 100)

Variable	1990	2005	2017	2018	2019	2020	2021	Avg. Annual Growth Rate Since 1990[a]	Avg. Annual Growth Rate Since 2005[a]

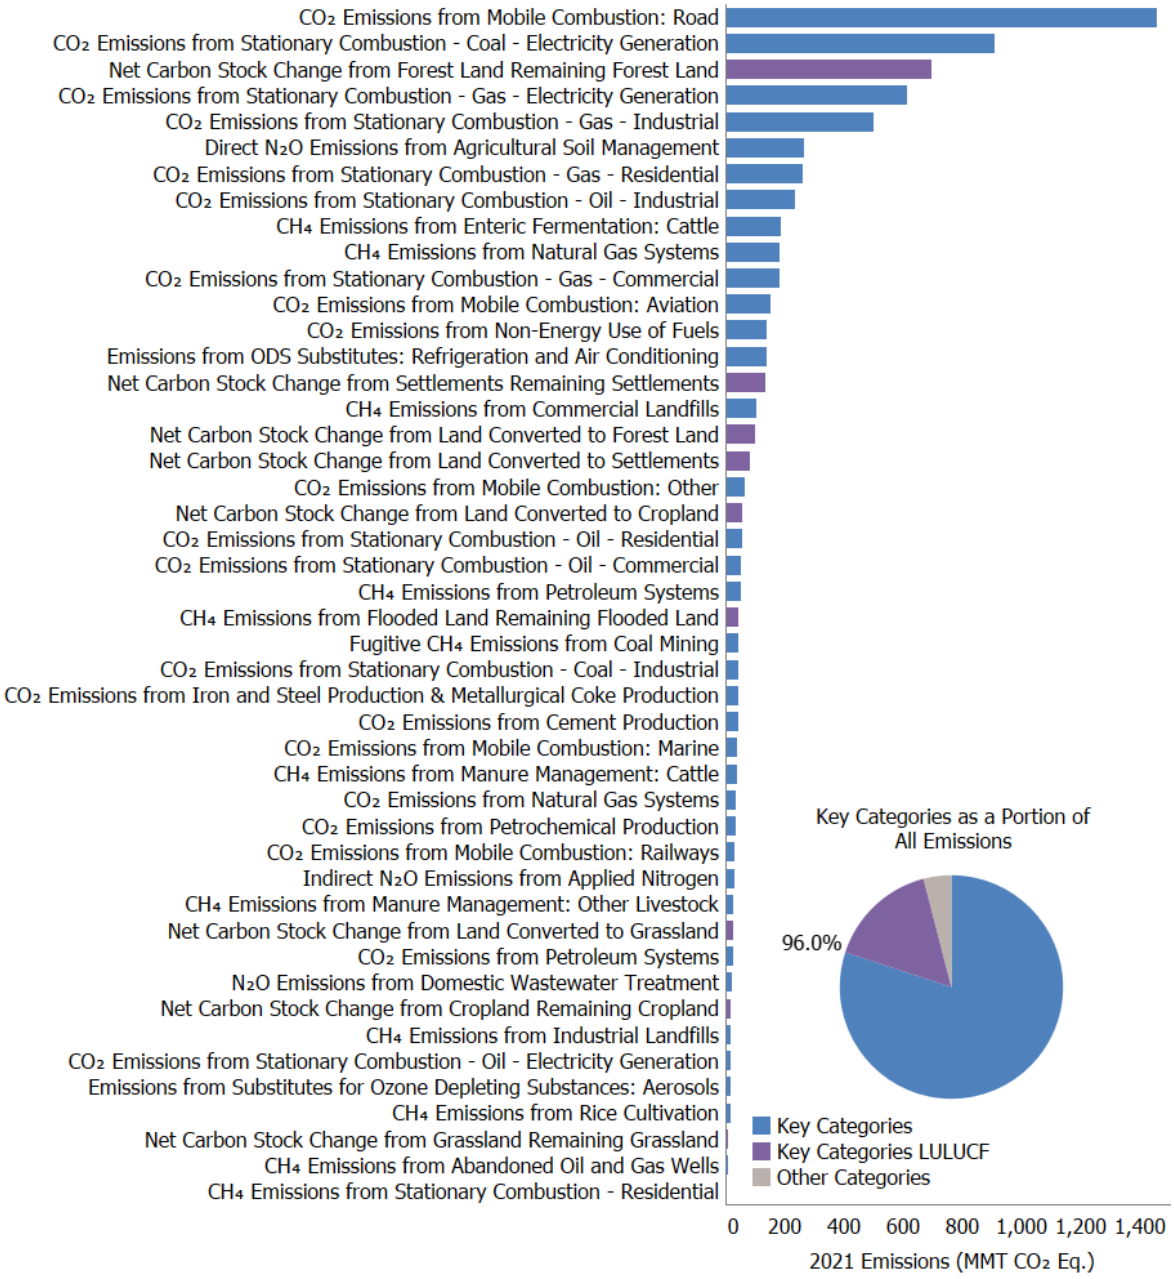
Key Categories



The *2006 IPCC Guidelines* (IPCC 2006) and *2019 Refinement to the 2006 IPCC Guidelines* (IPCC 2019) defines key categories as "inventory categories which individually, or as a group of categories (for which a common method, emission factor and activity data are applied) are prioritized within the national inventory system because their estimates have a significant influence on a country's total inventory of greenhouse gases in terms of the absolute level, the trend, or the level of uncertainty in emissions or removals."[26] A key category analysis identifies priority source or sink categories for focusing efforts to improve overall Inventory quality. In addition, a qualitative review of key categories and non-key categories can also help identify additional source and sink categories to consider for improvement efforts, including reducing uncertainty.

Figure ES-16 presents the 2021 key categories identified by the Approach 1 level assessment, including the LULUCF sector. A level assessment using Approach 1 identifies all source and sink categories that cumulatively account for 95 percent of total (i.e., gross) emissions in a given year when assessed in descending order of absolute magnitude.

[26] See Chapter 4 "Methodological Choice and Identification of Key Categories" in IPCC (2006) and IPCC (2019). See http://www.ipcc-nggip.iges.or.jp/public/2006gl/vol1.html and https://www.ipcc-nggip.iges.or.jp/public/2019rf/pdf/1_Volume1/19R_V1_Ch04_MethodChoice.pdf.

For a complete list of key categories and more information regarding the overall key category analysis, including approaches accounting for uncertainty and the influence of trends of individual source and sink categories, see the Introduction chapter, Section 1.5 – Key Categories and Annex 1.

Figure ES-16: 2021 Key Categories (Approach 1 including LULUCF)[a]

[a] For a complete list of key categories and detailed discussion of the underlying key category analysis, see Annex 1. Bars indicate key categories identified using Approach 1 level assessment including the LULUCF sector. The absolute values of net CO_2

emissions from LULUCF are presented in this figure but reported separately from gross emissions totals. Refer to Table ES-4 for a breakout of emissions and removals for LULUCF by source/sink category.

Quality Assurance and Quality Control (QA/QC)

The United States seeks continuous improvements to the quality, transparency, and usability of the *Inventory of U.S. Greenhouse Gas Emissions and Sinks*. To assist in these efforts, the United States implemented a systematic approach to QA/QC. The procedures followed for the Inventory have been formalized in accordance with the U.S. Inventory QA/QC plan, and the UNFCCC reporting guidelines and *2006 IPCC Guidelines*. The QA process includes expert and public reviews for the Inventory estimates and this report.

Box ES-3: Use of Ambient Measurements Systems for Validation of Emission Inventories

In following the UNFCCC requirement under Article 4.1 to develop and submit national greenhouse gas emission inventories, the emissions and sinks presented in this report are organized by source and sink categories and calculated using internationally accepted methods provided by the IPCC.[27] Several recent studies have estimated emissions at the national or regional level with estimated results that sometimes differ from EPA's estimate of emissions. EPA has engaged with researchers on how remote sensing, ambient measurement, and inverse modeling techniques for estimating greenhouse gas emissions could assist in improving the understanding of inventory estimates. In working with the research community to improve national greenhouse gas inventories, EPA follows guidance from the IPCC on the use of measurements and modeling to validate emission inventories.[28] An area of particular interest in EPA's outreach efforts is how ambient measurement data can be used to assess estimates or potentially be incorporated into the Inventory in a manner consistent with this Inventory report's transparency of its calculation methodologies, and the ability of inverse modeling techniques to attribute emissions and removals from remote sensing to anthropogenic sources, as defined by the IPCC for this report, versus natural sources and sinks.

The *2019 Refinement to the IPCC 2006 Guidelines for National Greenhouse Gas Inventories* (IPCC 2019) Volume 1 General Guidance and Reporting, Chapter 6: Quality Assurance, Quality Control and Verification notes that atmospheric concentration measurements can provide independent data sets as a basis for comparison with inventory estimates. The *2019 Refinement* provides guidance on conducting such comparisons (as summarized in Table 6.2 of IPCC [2019] Volume 1, Chapter 6) and provides guidance on using such comparisons to identify areas of improvement in national inventories (as summarized in Box 6.5 of IPCC [2019] Volume 1, Chapter 6) given the technical complexity of such comparisons. Further, it identified fluorinated gases as particularly suitable for such comparisons. The *2019 Refinement* makes this conclusion for fluorinated gases based on their lack of significant natural sources, their generally long atmospheric lifetimes, their well-known loss mechanisms, and the potential uncertainties in bottom-up inventory methods for some of their sources. Unlike emissions of CO_2, CH_4, and N_2O, emissions of fluorinated greenhouse gases are almost exclusively anthropogenic, meaning that the fluorinated greenhouse gas emission sources included in this Inventory account for the majority of the total U.S. emissions of these gases detectable in the atmosphere.

In this Inventory, EPA presents the results of two comparisons between fluorinated gas emissions inferred from atmospheric measurements and fluorinated gas emissions estimated based on bottom-up measurements and modeling. These comparisons, performed for HFCs and SF_6 respectively, are described under the QA/QC and Verification discussions in Chapter 4, Sections 4.24 Substitution of Ozone Depleting Substances and 4.25 Electrical Transmission and Distribution in the IPPU chapter of this report.

Consistent with the *2019 Refinement*, a key element to facilitate such comparisons is a gridded prior inventory as an input to inverse modeling. To improve the ability to compare the national-level greenhouse gas inventory with measurement results that may be at other scales, a team at Harvard University along with EPA and other

[27] See http://www.ipcc-nggip.iges.or.jp/public/index.html.

[28] See http://www.ipcc-nggip.iges.or.jp/meeting/pdfiles/1003_Uncertainty%20meeting_report.pdf.

coauthors developed a gridded inventory of U.S. anthropogenic methane emissions with 0.1° x 0.1° spatial resolution, monthly temporal resolution, and detailed scale-dependent error characterization. The gridded inventory is designed to be consistent with the 1990 to 2014 U.S. EPA *Inventory of U.S. Greenhouse Gas Emissions and Sinks* estimates for the year 2012, which presents national totals for different source types.[29] This gridded inventory is consistent with the recommendations contained in two National Academies of Science reports examining greenhouse gas emissions data (National Research Council 2010; National Academies of Sciences, Engineering, and Medicine 2018).

Finally, in addition to use of atmospheric concentration measurement data for comparison with Inventory data, information from top-down studies is directly incorporated in the Natural Gas Systems calculations to quantify emissions from certain well blowout events.

Uncertainty Analysis of Emission and Sink Estimates

Uncertainty assessment is an essential element of a complete inventory of greenhouse gas emissions and removals because it helps to inform and prioritize inventory improvements. Recognizing the benefit of conducting an uncertainty analysis, the UNFCCC reporting guidelines follow the recommendations of the *2006 IPCC Guidelines* (IPCC 2006), Volume 1, Chapter 3 and require that countries provide single estimates of uncertainty for source and sink categories. In addition to quantitative uncertainty assessments, a qualitative discussion of uncertainty is presented for each source and sink category identifying specific factors affecting the uncertainty surrounding the estimates provided in accordance with UNFCCC reporting guidelines. Some of the current estimates, such as those for CO_2 emissions from energy-related combustion activities, are considered to have low uncertainties. This is because the amount of CO_2 emitted from energy-related combustion activities is directly related to the amount of fuel consumed, the fraction of the fuel that is oxidized, and the carbon content of the fuel, and for the United States, the uncertainties associated with estimating those factors is relatively small. For some other categories of emissions and sinks, however, inherent variability or a lack of data increases the uncertainty or systematic error associated with the estimates presented. Finally, an analysis is conducted to assess uncertainties associated with the overall emissions, sinks and trends estimates. The overall uncertainty surrounding total net greenhouse gas emissions is estimated to be -5 to +6 percent in 1990 and -4 to +6 percent in 2021. When the LULUCF sector is excluded from the analysis the uncertainty is estimated to be -2 to +5 percent in 1990 and -2 to +6 percent in 2021.

[29] See https://www.epa.gov/ghgemissions/gridded-2012-methane-emissions.

1. Introduction

This report presents an inventory of U.S. anthropogenic greenhouse gas emissions and sinks for the years 1990 through 2021 compiled by the United States government. A summary of these estimates is provided in Table 2-1 and Table 2-2 by gas and source category in the Trends in Greenhouse Gas Emissions chapter. The emission and sink estimates in these tables are presented on both a full mass basis and on a global warming potential (GWP)-weighted basis[1] in order to show the relative contribution of each gas to global average radiative forcing. This report also discusses the methods and data used to calculate the emission and sink estimates.

In 1992, the United States signed and ratified the United Nations Framework Convention on Climate Change (UNFCCC). As stated in Article 2 of the UNFCCC, "The ultimate objective of this Convention and any related legal instruments that the Conference of the Parties may adopt is to achieve, in accordance with the relevant provisions of the Convention, stabilization of greenhouse gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system. Such a level should be achieved within a time-frame sufficient to allow ecosystems to adapt naturally to climate change, to ensure that food production is not threatened and to enable economic development to proceed in a sustainable manner."[2,3]

As a signatory to the UNFCCC, consistent with Article 4[4] and decisions at the First, Second, Fifth, and Nineteenth Conference of Parties,[5] the U.S. is committed to submitting a national inventory of anthropogenic sources and sinks of greenhouse gases to the UNFCCC by April 15 of each year. This Inventory provides a national estimate of sources and sinks for the United States, including all states, the District of Columbia and U.S. Territories.[6] The United States views this report, in conjunction with Common Reporting Format (CRF) reporting tables that accompany this report, as an opportunity to fulfill this annual commitment under the UNFCCC. Overall, this

See more information on completeness in Section 1.8.

Inventory of anthropogenic greenhouse gas emissions and sinks provides a common and consistent mechanism through which Parties to the UNFCCC can compare the relative contribution of individual sources, gases, and nations to climate change. The structure of this report is consistent with the current UNFCCC Guidelines on Annual Inventories (UNFCCC 2014) for Parties included in Annex I of the Convention.

In 1988, preceding the creation of the UNFCCC, the World Meteorological Organization (WMO) and the United Nations Environment Programme (UNEP) jointly established the Intergovernmental Panel on Climate Change (IPCC). The role of the IPCC is to assess on a comprehensive, objective, open and transparent basis the scientific, technical and socio-economic information relevant to understanding the scientific basis of risk of human-induced climate change, its potential impacts and options for adaptation and mitigation (IPCC 2021). Under Working Group 1 of the IPCC, nearly 140 scientists and national experts from more than thirty countries collaborated in the creation of the *Revised 1996 IPCC Guidelines for National Greenhouse Gas Inventories* (IPCC/UNEP/OECD/IEA 1997) to ensure that the emission inventories submitted to the UNFCCC are consistent and comparable between nations. The *IPCC Good Practice Guidance and Uncertainty Management in National Greenhouse Gas Inventories* and the *IPCC Good Practice Guidance for Land Use, Land-Use Change, and Forestry* further expanded upon the methodologies in the *Revised 1996 IPCC Guidelines*. In 2006, the IPCC accepted the *2006 Guidelines for National Greenhouse Gas Inventories* at its Twenty-Fifth Session (Mauritius, April 2006). The *2006 IPCC Guidelines* built upon the previous bodies of work and include new sources and gases, "…as well as updates to the previously published methods whenever scientific and technical knowledge have improved since the previous guidelines were issued." The UNFCCC adopted the *2006 IPCC Guidelines* as the standard methodological approach for Annex I countries and encouraged countries to gain experience in using the *2013 Supplement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories: Wetlands* at the Nineteenth Conference of the Parties (Warsaw, November 11-23, 2013). The IPCC has recently released the *2019 Refinement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories* to clarify and elaborate on the existing guidance in the *2006 IPCC Guidelines*, along with providing updates to default values of emission factors and other parameters based on updated science. This report applies both the *2013 Supplement* and updated guidance in the *2019 Refinement* to improve accuracy and completeness of the Inventory. For more information on specific uses see Section 1.4 of this chapter on Methodology and Data Sources.

Box 1-1: Methodological Approach for Estimating and Reporting U.S. Emissions and Removals, including Relationship to EPA's Greenhouse Gas Reporting Program

In following the UNFCCC requirement under Article 4.1 and decision 24/CP.19 to develop and submit annual national greenhouse gas emission inventories, the emissions and removals presented in this report and this chapter are organized by source and sink categories and calculated using internationally-accepted methods provided by the IPCC in the *2006 IPCC Guidelines for National Greenhouse Gas Inventories (2006 IPCC Guidelines)* and where appropriate, its supplements and refinements. Additionally, the calculated emissions and removals in a given year for the United States are presented in a common format in line with the UNFCCC reporting guidelines for the reporting of inventories under this international agreement. The use of consistent methods to calculate emissions and removals by all nations reporting their inventories to the UNFCCC ensures that the estimates are comparable. The presentation of emissions and removals provided in this Inventory does not preclude alternative examinations, but rather this Inventory presents emissions and removals in a common format consistent with how countries are to report Inventories under the UNFCCC. The report itself, and this chapter, follows this standardized format, and provides an explanation of the application of methods used to calculate emissions and removals.

EPA also collects greenhouse gas emissions data from individual facilities and suppliers of certain fossil fuels and industrial gases through its Greenhouse Gas Reporting Program (GHGRP).[7] The GHGRP applies to direct greenhouse gas emitters, fossil fuel suppliers, industrial gas suppliers, and facilities that inject carbon dioxide

[7] On October 30, 2009, the EPA promulgated a rule requiring annual reporting of greenhouse gas data from large greenhouse gas emissions sources in the United States. Implementation of the rule, codified at 40 CFR Part 98, is referred to as EPA's Greenhouse Gas Reporting Program (GHGRP).

(CO_2) underground for sequestration or other reasons and requires reporting by over 8,000 sources or suppliers in 41 industrial categories.[8] Annual reporting is at the facility level, except for certain suppliers of fossil fuels and industrial greenhouse gases. In general, the threshold for reporting is 25,000 metric tons or more of CO_2 Eq. per year. Facilities in most source categories subject to GHGRP began reporting for the 2010 reporting year while additional types of industrial operations began reporting for reporting year 2011. While the GHGRP does not provide full coverage of total annual U.S. greenhouse gas emissions and sinks (e.g., the GHGRP excludes emissions from the agricultural, land use, and forestry sectors), it is an important input to the calculations of national-level emissions in the Inventory.

Data presented in this Inventory report and EPA's GHGRP are complementary. The GHGRP dataset continues to be an important resource for the Inventory, providing not only annual emissions information, but also other annual information such as activity data and emission factors that can improve and refine national emission estimates and trends over time. Methodologies used in EPA's GHGRP are consistent with the *2006 IPCC Guidelines* (e.g., higher tier methods). GHGRP data also allow EPA to disaggregate national inventory estimates in new ways that can highlight differences across regions and sub-categories of emissions, along with enhancing the application of QA/QC procedures and assessment of uncertainties. EPA uses annual GHGRP data in a number of categories to improve the national estimates presented in this Inventory consistent with IPCC methodological guidance. See Annex 9 for more information on specific uses of GHGRP data in the Inventory (e.g., natural gas systems).

1.1 Background Information

Science

For over the past 200 years, the burning of fossil fuels such as coal and oil, along with deforestation, land-use changes, and other activities have caused the concentrations of heat-trapping "greenhouse gases" to increase significantly in our atmosphere (IPCC 2021). These gases in the atmosphere absorb some of the energy being radiated from the surface of the Earth that would otherwise be lost to space, essentially acting like a blanket that makes the Earth's surface warmer than it would be otherwise.

Greenhouse gases are necessary to life as we know it. Without greenhouse gases to create the natural heat-trapping properties of the atmosphere, the planet's surface would be about 60 degrees Fahrenheit cooler than present (USGCRP 2017). Carbon dioxide is also necessary for plant growth. With emissions from biological and geological sources, there is a natural level of greenhouse gases that is maintained in the atmosphere. Human emissions of greenhouse gases and subsequent changes in atmospheric concentrations alter the balance of energy transfers between space and the earth system (IPCC 2021). A gauge of these changes is called radiative forcing, which is a measure of a substance's total net effect on the global energy balance for which a positive number represents a warming effect, and a negative number represents a cooling effect (IPCC 2021). IPCC concluded in its most recent scientific assessment report that it is "unequivocal that human influence has warmed the atmosphere, ocean and land" (IPCC 2021).

As concentrations of greenhouse gases continue to increase in from man-made sources, the Earth's temperature is climbing above past levels. The Earth's average land and ocean surface temperature has increased by about 2.0 degrees Fahrenheit from the 1850 to 1900 period to the decade of 2011 to 2020 (IPCC 2021). The last four decades have each been the warmest decade successively at the Earth's surface since at least 1850 (IPCC 2021). Other aspects of the climate are also changing, such as rainfall patterns, snow and ice cover, and sea level. If greenhouse gas concentrations continue to increase, climate models predict that the average temperature at the Earth's

[8] See http://www.epa.gov/ghgreporting and http://ghgdata.epa.gov/ghgp/main.do.

surface is likely to increase by up to 8.3 degrees Fahrenheit above 2011 to 2020 levels by the end of this century, depending on future emissions and the responsiveness of the climate system (IPCC 2021), though the lowest emission scenario would limit future warming to an additional 0.5 degrees (best estimate).

For further information on greenhouse gases, radiative forcing, and implications for climate change, see the recent scientific assessment reports from the IPCC,[9] the U.S. Global Change Research Program (USGCRP),[10] and the National Academies of Sciences, Engineering, and Medicine (NAS).[11]

Greenhouse Gases

Although the Earth's atmosphere consists mainly of oxygen and nitrogen, neither plays a significant role in enhancing the greenhouse effect because both are essentially transparent to terrestrial radiation. The greenhouse effect is primarily a function of the concentration of water vapor, carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), and other trace gases in the atmosphere that absorb the terrestrial radiation leaving the surface of the Earth (IPCC 2021).

Naturally occurring greenhouse gases include water vapor, CO_2, CH_4, N_2O, and ozone (O_3). Several classes of halogenated substances that contain fluorine, chlorine, or bromine are also greenhouse gases, but they are, for the most part, solely a product of industrial activities. Chlorofluorocarbons (CFCs) and hydrochlorofluorocarbons (HCFCs) are halocarbons that contain chlorine, while halocarbons that contain bromine are referred to as bromofluorocarbons (i.e., halons). As stratospheric ozone depleting substances, CFCs, HCFCs, and halons are covered under the Montreal Protocol on Substances that Deplete the Ozone Layer. The UNFCCC defers to this earlier international treaty. Consequently, Parties to the UNFCCC are not required to include these gases in national greenhouse gas inventories.[12] Some other fluorine-containing halogenated substances—hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), sulfur hexafluoride (SF_6), and nitrogen trifluoride (NF_3)—do not deplete stratospheric ozone but are potent greenhouse gases. These latter substances are addressed by the UNFCCC and accounted for in national greenhouse gas inventories.

There are also several other substances that influence the global radiation budget but are short-lived and therefore not well-mixed, leading to spatially variable radiative forcing effects. These substances include carbon monoxide (CO), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), and tropospheric (ground level) ozone (O_3). Tropospheric ozone is formed from chemical reactions in the atmosphere of precursor pollutants, which include volatile organic compounds (VOCs, including CH_4) and nitrogen oxides (NO_x), in the presence of ultraviolet light (sunlight).

Aerosols are extremely small particles or liquid droplets suspended in the Earth's atmosphere that are often composed of sulfur compounds, carbonaceous combustion products (e.g., black carbon), crustal materials (e.g., dust) and other human-induced pollutants. They can affect the absorptive characteristics of the atmosphere (e.g., scattering incoming sunlight away from the Earth's surface, or, in the case of black carbon, absorb sunlight) and can play a role in affecting cloud formation and lifetime, as well as the radiative forcing of clouds and precipitation patterns.

Carbon dioxide, CH_4, and N_2O are continuously emitted to and removed from the atmosphere by natural processes on Earth. Anthropogenic activities (such as fossil fuel combustion, cement production, land-use, land-use change, and forestry, agriculture, or waste management), however, can cause additional quantities of these and other greenhouse gases to be emitted or sequestered, thereby changing their global average atmospheric

[9] See https://www.ipcc.ch/report/ar6/wg1/.

[10] See https://nca2018.globalchange.gov/.

[11] See https://www.nationalacademies.org/topics/climate.

[12] Emissions estimates of CFCs, HCFCs, halons and other ozone-depleting substances are included in this document for informational purposes.

concentrations. Natural activities such as respiration by plants or animals and seasonal cycles of plant growth and decay are examples of processes that only cycle carbon or nitrogen between the atmosphere and organic biomass. Such processes, except when directly or indirectly perturbed out of equilibrium by anthropogenic activities, generally do not alter average atmospheric greenhouse gas concentrations over decadal timeframes. Climatic changes resulting from anthropogenic activities, however, could have positive or negative feedback effects on these natural systems. Atmospheric concentrations of these gases, along with their rates of growth and atmospheric lifetimes, are presented in Table 1-1.

Table 1-1: Global Atmospheric Concentration, Rate of Concentration Change, and Atmospheric Lifetime of Selected Greenhouse Gases

Atmospheric Variable	CO_2	CH_4	N_2O	SF_6	CF_4
Pre-industrial atmospheric concentration	280 ppm	0.730 ppm	0.270 ppm	0 ppt	40 ppt
Atmospheric concentration	416 ppm[a]	1.895 ppm[b]	0.334 ppm[c]	10.63 ppt[d]	85.5 ppt[e]
Rate of concentration change	2.38 ppm/yr[f]	18.05 ppb/yr[f,g]	1.30 ppb/yr[f]	0.39 ppt/yr[f]	0.81 ppt/yr[f]
Atmospheric lifetime (years)	See footnote[h]	11.8	109[i]	About 1,000[j]	50,000

[a] The atmospheric CO_2 concentration is the 2021 annual average at the Mauna Loa, HI station (NOAA/ESRL 2023a). The global atmospheric CO_2 concentration, computed using an average of sampling sites across the world, was 415 ppm in 2021.

[b] The values presented are global 2021 annual average mole fractions (NOAA/ESRL 2023b).

[c] The values presented are global 2021 annual average mole fractions (NOAA/ESRL 2023c).

[d] The values presented are global 2021 annual average mole fractions (NOAA/ESRL 2023d).

[e] The 2019 CF_4 global mean atmospheric concentration is from the Advanced Global Atmospheric Gases Experiment (IPCC 2021).

[f] The rate of concentration change for CO_2 is an average of the rates from 2007 through 2021 and has fluctuated between 1.5 to 3.0 ppm per year over this period (NOAA/ESRL 2023a). The rate of concentration change for CH_4, N_2O, and SF_6, is the average rate of change between 2007 and 2021 (NOAA/ESRL 2023b; NOAA/ESRL 2023c; NOAA/ESRL 2023d). The rate of concentration change for CF_4 is the average rate of change between 2011 and 2019 (IPCC 2021).

[g] The growth rate for atmospheric CH_4 decreased from over 10 ppb/year in the 1980s to nearly zero in the early 2000s; recently, the growth rate has been about 18.21 ppb/year (NOAA/ESRL 2023b).

[h] For a given amount of CO_2 emitted, some fraction of the atmospheric increase in concentration is quickly absorbed by the oceans and terrestrial vegetation, some fraction of the atmospheric increase will only slowly decrease over a number of years, and a small portion of the increase will remain for many centuries or more.

[i] This lifetime has been defined as an "adjustment time" that takes into account the indirect effect of the gas on its own residence time.

[j] The lifetime for SF_6 was revised from 3,200 years to about 1,000 years based on recent studies (IPCC 2021).

Source: Pre-industrial atmospheric concentrations and atmospheric lifetimes for CH_4, N_2O, SF_6, and CF_4 are from IPCC (2021).

A brief description of each greenhouse gas, its sources, and its role in the atmosphere is given below. The following section then explains the concept of GWPs, which are assigned to individual gases as a measure of their relative average global radiative forcing effect.

Water Vapor (H_2O). Water vapor is the largest contributor to the natural greenhouse effect. Water vapor is fundamentally different from other greenhouse gases in that it can condense and rain out when it reaches high concentrations, and the total amount of water vapor in the atmosphere is in part a function of the Earth's temperature. While some human activities such as evaporation from irrigated crops or power plant cooling release water vapor into the air, these activities have been determined to have a negligible effect on global climate (IPCC 2021). The lifetime of water vapor in the troposphere is on the order of 10 days. Water vapor can also contribute to cloud formation, and clouds can have both warming and cooling effects by either trapping or reflecting heat. Because of the relationship between water vapor levels and temperature, water vapor and clouds serve as a feedback to climate change, such that for any given increase in other greenhouse gases, the total warming is greater than would happen in the absence of water vapor. Aircraft emissions of water vapor can create contrails, which may also develop into contrail-induced cirrus clouds, with complex regional and temporal net radiative forcing effects that currently have a low level of scientific certainty (IPCC 2021).

Carbon Dioxide (CO_2). In nature, carbon is cycled between various atmospheric, oceanic, land biotic, marine biotic, and mineral reservoirs. The largest fluxes occur between the atmosphere and terrestrial biota, and between the atmosphere and surface water of the oceans. In the atmosphere, carbon predominantly exists in its oxidized form

as CO_2. Atmospheric CO_2 is part of this global carbon cycle, and therefore its fate is a complex function of geochemical and biological processes. Carbon dioxide concentrations in the atmosphere increased from approximately 280 parts per million by volume (ppmv) in pre-industrial times to 416 ppmv in 2021, a 48 percent increase (IPCC 2021; NOAA/ESRL 2023a).[13,14] The IPCC states that "Observed increases in well-mixed greenhouse gas (GHG) concentrations since around 1750 are unequivocally caused by human activities" (IPCC 2021). The predominant source of anthropogenic CO_2 emissions is the combustion of fossil fuels. Forest clearing, other biomass burning, and some non-energy production processes (e.g., cement production) also emit notable quantities of CO_2. In its *Sixth Assessment Report*, the IPCC determined that of the 2.0 degrees of observed warming, the best estimate is that 1.9 degrees of that are due to human influence, with elevated CO_2 concentrations being the most important contributor to that warming (IPCC 2021).

Methane (CH_4). Methane is primarily produced through anaerobic decomposition of organic matter in biological systems. Agricultural processes such as wetland rice cultivation, enteric fermentation in animals, and the decomposition of animal wastes emit CH_4, as does the decomposition of municipal solid wastes and treatment of wastewater. Methane is also emitted during the production and distribution of natural gas and petroleum, and is released as a byproduct of coal mining and incomplete fossil fuel combustion. Atmospheric concentrations of CH_4 have increased by about 162 percent since 1750, from a pre-industrial value of about 730 ppb to 1,895 ppb in 2021[15] although the rate of increase decreased to near zero in the early 2000s, and has recently increased again to about 18.05 ppb/year. The IPCC has estimated that about half of the current CH_4 flux to the atmosphere (and the entirety of the increase in concentration) is anthropogenic, from human activities such as agriculture, fossil fuel production and use, and waste disposal (IPCC 2021).

Methane is primarily removed from the atmosphere through a reaction with the hydroxyl radical (OH) and is ultimately converted to CO_2. Minor removal processes also include reaction with chlorine in the marine boundary layer, a soil sink, and stratospheric reactions. Increasing emissions of CH_4 reduce the concentration of OH, a feedback that increases the atmospheric lifetime of CH_4 (IPCC 2021). Methane's reactions in the atmosphere also lead to production of tropospheric ozone and stratospheric water vapor, both of which also contribute to climate change. Tropospheric ozone also has negative effects on human health and plant productivity.

Nitrous Oxide (N_2O). Anthropogenic sources of N_2O emissions include agricultural soils, especially production of nitrogen-fixing crops and forages, the use of synthetic and manure fertilizers, and manure deposition by livestock; fossil fuel combustion, especially from mobile combustion; adipic (nylon) and nitric acid production; wastewater treatment and waste incineration; and biomass burning. The atmospheric concentration of N_2O has increased by 24 percent since 1750, from a pre-industrial value of about 270 ppb to 334 ppb in 2021,[16] a concentration that has not been exceeded during at least the last 800 thousand years. Nitrous oxide is primarily removed from the atmosphere by the photolytic action of sunlight in the stratosphere (IPCC 2021).

Ozone (O_3). Ozone is present in both the upper stratosphere,[17] where it shields the Earth from harmful levels of ultraviolet radiation, and at lower concentrations in the troposphere,[18] where it is the main component of

[13] The pre-industrial period is considered as the time preceding the year 1750 (IPCC 2013).

[14] Carbon dioxide concentrations during the last 1,000 years of the pre-industrial period (i.e., 750 to 1750), a time of relative climate stability, fluctuated by about ±10 ppmv around 280 ppmv (IPCC 2013).

[15] This value is the global 2021 annual average mole fraction (NOAA/ESRL 2023b).

[16] This value is the global 2021 annual average (NOAA/ESRL 2023c).

[17] The stratosphere is the layer from the troposphere up to roughly 50 kilometers. In the lower regions the temperature is nearly constant but in the upper layer the temperature increases rapidly because of sunlight absorption by the ozone layer. The ozone-layer is the part of the stratosphere from 19 kilometers up to 48 kilometers where the concentration of ozone reaches up to 10 parts per million.

[18] The troposphere is the layer from the ground up to 11 kilometers near the poles and up to 16 kilometers in equatorial regions (i.e., the lowest layer of the atmosphere where people live). It contains roughly 80 percent of the mass of all gases in the atmosphere and is the site for most weather processes, including most of the water vapor and clouds.

anthropogenic photochemical "smog." During the last two decades, emissions of anthropogenic chlorine and bromine-containing halocarbons, such as CFCs, have depleted stratospheric ozone concentrations. This loss of ozone in the stratosphere has resulted in negative radiative forcing, representing an indirect effect of anthropogenic emissions of chlorine and bromine compounds (IPCC 2021). The depletion of stratospheric ozone and its radiative forcing remained relatively unchanged since 2000 for the last two decades and is starting to decline; recovery is expected to occur shortly after the middle of the twenty-first century (WMO/UNEP 2018).

The past increase in tropospheric ozone, which is also a greenhouse gas, is estimated to provide the third largest increase in direct radiative forcing since the pre-industrial era, behind CO_2 and CH_4. Tropospheric ozone is produced from complex chemical reactions of volatile organic compounds (including CH_4) mixing with NO_x in the presence of sunlight. The tropospheric concentrations of ozone and these other pollutants are short-lived and, therefore, spatially variable (IPCC 2021).

Halocarbons, Sulfur Hexafluoride, and Nitrogen Trifluoride. Halocarbons are, for the most part, man-made chemicals that have direct radiative forcing effects and could also have an indirect effect. Halocarbons that contain chlorine (CFCs, HCFCs, methyl chloroform, and carbon tetrachloride) and bromine (halons, methyl bromide, and hydrobromofluorocarbons) result in stratospheric ozone depletion and are therefore controlled under the Montreal Protocol on Substances that Deplete the Ozone Layer. Although most CFCs and HCFCs are potent global warming gases, their net radiative forcing effect on the atmosphere is reduced because they cause stratospheric ozone depletion, which itself is a greenhouse gas but which also shields the Earth from harmful levels of ultraviolet radiation. Under the Montreal Protocol, the United States phased out the production and importation of halons by 1994 and of CFCs by 1996. Under the Copenhagen Amendments to the Protocol, a cap was placed on the production and importation of HCFCs by non-Article 5 countries, including the United States,[19] beginning in 1996, and then followed by intermediate requirements and a complete phase-out by the year 2030. While ozone depleting gases covered under the Montreal Protocol and its Amendments are not covered by the UNFCCC, they are reported in this Inventory under Annex 6.2 for informational purposes.

Hydrofluorocarbons, PFCs, SF_6, and NF_3 are not ozone depleting substances. The most common HFCs are, however, powerful greenhouse gases. Hydrofluorocarbons are primarily used as replacements for ozone depleting substances but also emitted as a byproduct of the HCFC-22 (chlorodifluoromethane) manufacturing process. Currently, they have a small aggregate radiative forcing impact, but it is anticipated that without further controls their contribution to overall radiative forcing will increase, the ERF (effective radiative forcing) of halogenated gases increased by 3.5 percent between 2011 and 2019 primarily due to a decrease in atmospheric mixing-ratios of CFCs and an increase in their replacements (IPCC 2021). On December 27, 2020, the American Innovation and Manufacturing (AIM) Act was enacted by Congress and which gives EPA authority to phase down HFC production and consumption (i.e., production plus import, minus export), through an allowance allocation program, promulgate certain regulations for purposes of maximizing reclamation and minimizing releases of HFCs and their substitutes from equipment, and facilitating the transition to next-generation technologies through sector-based restrictions, which will lead to lower HFC emissions over time. Perfluorocarbons, SF_6, and NF_3 are predominantly emitted from various industrial processes including aluminum smelting, semiconductor manufacturing, electric power transmission and distribution, and magnesium casting. Currently, the radiative forcing impact of PFCs, SF_6, and NF_3 is also small, but they have a significant growth rate, extremely long atmospheric lifetimes, and are strong absorbers of infrared radiation, and therefore have the potential to influence climate far into the future (IPCC 2021).

Carbon Monoxide (CO). Carbon monoxide has an indirect radiative forcing effect by elevating concentrations of CH_4 and tropospheric ozone through chemical reactions with other atmospheric constituents (e.g., the hydroxyl radical, OH) that would otherwise assist in destroying CH_4 and tropospheric ozone. Carbon monoxide is created when

[19] Article 5 of the Montreal Protocol covers several groups of countries, especially developing countries, with low consumption rates of ozone depleting substances. Developing countries with per capita consumption of less than 0.3 kg of certain ozone depleting substances (weighted by their ozone depleting potential) receive financial assistance and a grace period of ten additional years in the phase-out of ozone depleting substances.

carbon-containing fuels are burned incompletely. Through natural processes in the atmosphere, it is eventually oxidized to CO_2. Carbon monoxide concentrations are both short-lived in the atmosphere and spatially variable.

Nitrogen Oxides (NO_x). The primary climate change effects of nitrogen oxides (i.e., NO and NO_2) are indirect. Warming effects can occur due to reactions leading to the formation of ozone in the troposphere, but cooling effects can occur due to the role of NO_x as a precursor to nitrate particles (i.e., aerosols) and due to destruction of stratospheric ozone when emitted from very high-altitude aircraft.[20] Additionally, NO_x emissions are also likely to decrease CH_4 concentrations, thus having a negative radiative forcing effect (IPCC 2021). Nitrogen oxides are created from lightning, soil microbial activity, biomass burning (both natural and anthropogenic fires) fuel combustion, and, in the stratosphere, from the photo-degradation of N_2O. Concentrations of NO_x are both relatively short-lived in the atmosphere and spatially variable.

Non-methane Volatile Organic Compounds (NMVOCs). Non-methane volatile organic compounds include substances such as propane, butane, and ethane. These compounds participate, along with NO_x, in the formation of tropospheric ozone and other photochemical oxidants. NMVOCs are emitted primarily from transportation and industrial processes, as well as biomass burning and non-industrial consumption of organic solvents. Concentrations of NMVOCs tend to be both short-lived in the atmosphere and spatially variable.

Aerosols. Aerosols are extremely small particles or liquid droplets found in the atmosphere that are either directly emitted into or are created through chemical reactions in the Earth's atmosphere. Aerosols or their chemical precursors can be emitted by natural events such as dust storms, biogenic or volcanic activity, or by anthropogenic processes such as transportation, coal combustion, cement manufacturing, waste incineration, or biomass burning. Various categories of aerosols exist from both natural and anthropogenic sources, such as soil dust, sea salt, biogenic aerosols, sulfates, nitrates, volcanic aerosols, industrial dust, and carbonaceous[21] aerosols (e.g., black carbon, organic carbon). Aerosols can be removed from the atmosphere relatively rapidly by precipitation or through more complex processes under dry conditions.

Aerosols affect radiative forcing differently than greenhouse gases. Their radiative effects occur through direct and indirect mechanisms: directly by scattering and absorbing solar radiation (and to a lesser extent scattering, absorption, and emission of terrestrial radiation); and indirectly by increasing cloud droplets and ice crystals that modify the formation, precipitation efficiency, and radiative properties of clouds (IPCC 2021). Despite advances in understanding of cloud-aerosol interactions, the contribution of aerosols to radiative forcing are difficult to quantify because aerosols generally have short atmospheric lifetimes, and have number concentrations, size distributions, and compositions that vary regionally, spatially, and temporally (IPCC 2021).

The net effect of aerosols on the Earth's radiative forcing is believed to be negative (i.e., net cooling effect on the climate). In fact, aerosols contributed a cooling influence of up to 1.4 degrees, offsetting a substantial portion of greenhouse gas warming (IPCC 2021). Because aerosols remain in the atmosphere for only days to weeks, their concentrations respond rapidly to changes in emissions.[22] Not all aerosols have a cooling effect. Current research suggests that another constituent of aerosols, black carbon, has a positive radiative forcing by heating the Earth's atmosphere and causing surface warming when deposited on ice and snow (IPCC 2021). Black carbon also influences cloud development, but the direction and magnitude of this forcing is an area of active research.

[20] NO_x emissions injected higher in the stratosphere, primarily from fuel combustion emissions from high altitude supersonic aircraft, can lead to stratospheric ozone depletion.

[21] Carbonaceous aerosols are aerosols that are comprised mainly of organic substances and forms of black carbon (or soot) (IPCC 2013).

[22] Volcanic activity can inject significant quantities of aerosol producing sulfur dioxide and other sulfur compounds into the stratosphere, which can result in a longer lasting negative forcing effect (i.e., a few years) (IPCC 2013).

Global Warming Potentials

A global warming potential (GWP) is a quantified measure of the globally averaged relative radiative forcing impacts of a particular greenhouse gas (see Table 1-2). It is defined as the accumulated radiative forcing within a specific time horizon caused by emitting 1 kilogram (kg) of the gas, relative to that of the reference gas CO_2 (IPCC 2021). Direct radiative effects occur when the gas itself absorbs radiation. Indirect radiative forcing occurs when chemical transformations involving the original gas produce a gas or gases that are greenhouse gases, or when a gas influences other radiatively important processes such as the atmospheric lifetimes of other gases. The reference gas used is CO_2, and therefore GWP-weighted emissions are measured in million metric tons of CO_2 equivalent (MMT CO_2 Eq.).[23] The relationship between kilotons (kt) of a gas and MMT CO_2 Eq. can be expressed as follows:

Equation 1-1: Calculating CO_2 Equivalent Emissions

$$\text{MMT CO}_2\text{ Eq.} = (\text{kt of gas}) \times (\text{GWP}) \times \left(\frac{\text{MMT}}{1{,}000\text{ kt}}\right)$$

where,

MMT CO_2 Eq.	= Million metric tons of CO_2 equivalent
kt	= kilotons (equivalent to a thousand metric tons)
GWP	= Global warming potential
MMT	= Million metric tons

GWP values allow for a comparison of the impacts of emissions and reductions of different gases. According to the IPCC, GWPs typically have an uncertainty of ±40 percent.

All estimates are provided throughout the report in both MMT CO_2 equivalents and unweighted units. Recent decisions under the UNFCCC require Parties to use 100-year GWP values from the IPCC *Fifth Assessment Report* (AR5) for calculating CO_2-equivalent emissions in their national reporting by the end of 2024.

> *…Decides that, until it adopts a further decision on the matter, the global warming potential values used by Parties in their reporting under the Convention to calculate the carbon dioxide equivalence of anthropogenic greenhouse gas emissions by sources and removals by sinks shall be based on the effects of greenhouse gases over a 100-year time horizon as listed in table 8.A.1 in appendix 8.A to the contribution of Working Group I to the Fifth Assessment Report of the Intergovernmental Panel on Climate Change,[24] excluding the value for fossil methane.*[25]

This reflects updated science and ensures that national greenhouse gas inventories reported by all nations are comparable. In preparation for upcoming UNFCCC requirement,[26] this report reflects CO_2-equivalent greenhouse gas totals using 100-year AR5 GWP values. A comparison of emission values with the previously used 100-year GWP values from IPCC *Fourth Assessment Report* (AR4) (IPCC 2007), and the IPCC *Sixth Assessment Report* (AR6)

The UNFCCC reporting guidelines require use of the 100-year GWPs listed in table 8.A.1 in Annex 8.A of Chapter 8 of the *Fifth Assessment Report* (AR5) of the Intergovernmental Panel on Climate Change, excluding the value for fossil methane. United Nations Framework Convention on Climate Change, see https://unfccc.int/sites/default/files/resource/cp2022_10a01_adv.pdf.

[26] See Annex to decision 18/CMA.1, available online at https://unfccc.int/sites/default/files/resource/CMA2018_03a02E.pdf

(IPCC 2021) values can be found in Annex 6.1 of this report. The 100-year GWP values used in this report are listed below in Table 1-2.

Greenhouse gases with relatively long atmospheric lifetimes (e.g., CO_2, CH_4, N_2O, HFCs, PFCs, SF_6, NF_3) tend to be evenly distributed throughout the atmosphere, and consequently global average concentrations can be determined. The short-lived gases such as water vapor, carbon monoxide, tropospheric ozone, ozone precursors (e.g., NO_x, and NMVOCs), and tropospheric aerosols (e.g., SO_2 products and carbonaceous particles), however, vary regionally, and consequently it is difficult to quantify their global radiative forcing impacts. Parties to the UNFCCC have not agreed upon GWP values for these gases that are short-lived and spatially inhomogeneous in the atmosphere.

Table 1-2: Global Warming Potentials and Atmospheric Lifetimes (Years) Used in this Report

Gas	Atmospheric Lifetime	GWP[a]
CO_2	See footnote[b]	1
CH_4[c]	12.4	28
N_2O	121	265
HFC-23	222	12,400
HFC-32	5.2	677
HFC-41[d]	2.8	116
HFC-125	28.2	3,170
HFC-134a	13.4	1,300
HFC-143a	47.1	4,800
HFC-152a	1.5	138
HFC-227ea	38.9	3,350
HFC-236fa	242	8,060
CF_4	50,000	6,630
C_2F_6	10,000	11,100
C_3F_8	2,600	8,900
c-C_4F_8	3,200	9,540
SF_6	3,200	23,500
NF_3	500	16,100
Other Fluorinated Gases		See Annex 6

[a] 100-year time horizon.

[b] For a given amount of CO_2 emitted, some fraction of the atmospheric increase in concentration is quickly absorbed by the oceans and terrestrial vegetation, some fraction of the atmospheric increase will only slowly decrease over a number of years, and a small portion of the increase will remain for many centuries or more.

[c] The GWP of CH_4 includes the direct effects and those indirect effects due to the production of tropospheric ozone and stratospheric water vapor. The indirect effect due to the production of CO_2 is not included.

Box 1-2: The IPCC Sixth Assessment Report and Global Warming Potentials

In 2021, the IPCC published its *Sixth Assessment Report* (AR6), which updated its comprehensive scientific assessment of climate change. Within the AR6 report, the GWP values of gases were revised relative to previous IPCC reports, namely the IPCC *Second Assessment Report* (SAR) (IPCC 1996), the IPCC *Third Assessment Report* (TAR) (IPCC 2001), the IPCC *Fourth Assessment Report* (AR4) (IPCC 2007), and the IPCC *Fifth Assessment Report* (AR5) (IPCC 2014). Although the AR5 GWP values are used throughout this report, consistent with UNFCCC reporting requirements, it is straight-forward to review the changes to the GWP values and their impact on

estimates of the total GWP-weighted emissions of the United States. In the AR6, the IPCC used more recent estimates of the atmospheric lifetimes and radiative efficiencies of some gases and updated background concentrations. The AR6 now includes climate-carbon feedback effects for non-CO_2 gases, improving the consistency between treatment of CO_2 and non-CO_2 gases. Indirect effects of gases on other atmospheric constituents (such as the effect of methane on ozone) have also been updated to match more recent science.

Table 1-3 presents the new GWP values, relative to those presented in the AR4 and AR5, using the 100-year time horizon common to UNFCCC reporting. For consistency with international reporting standards under the UNFCCC, official emission estimates are reported by the United States using AR4 100-year GWP values, as required by the 2013 revision to the UNFCCC reporting guidelines for national inventories.[27] Updated reporting guidelines under the Paris Agreement which require the United States and other countries to shift to use of the IPCC *Fifth Assessment Report* (AR5) (IPCC 2013) 100-year GWP values (without feedbacks) take effect for national inventory reporting in 2024.[28] All estimates provided throughout this report are also presented in unweighted units. For informational purposes, emission estimates that use 100-year GWPs from other recent IPCC Assessment Reports are presented in detail in Annex 6.1 of this report.

Table 1-3: Comparison of 100-Year GWP values

	100-Year GWP Values				Comparisons to AR5		
Gas	AR4	AR5[a]	AR5 with feedbacks[b]	AR6[c]	AR4	AR5 with feedbacks[b]	AR6[c]
CO_2	1	1	1	1	NC	NC	NC

SF_6	22,800	23,500	26,087	24,300	700	2,587	800
NF_3	17,200	16,100	17,885	17,400	(1,100)	1,785	1,300

NC (No Change)

[a] The GWP values in this column reflect values used in this report from AR5 excluding climate-carbon feedbacks and the value for fossil methane.

[b] The GWP values in this column are from the AR5 report but include climate-carbon feedbacks for the non-CO_2 gases in order to be consistent with the approach used in calculating the CO_2 lifetime.

[c] The GWP values in this column are from the AR6 report.

[d] The GWP of CH_4 includes the direct effects and those indirect effects due to the production of tropospheric ozone and stratospheric water vapor. Including the indirect effect due to the production of CO_2 resulting from methane oxidation would lead to an increase in AR5 methane GWP values by 2 for fossil methane and is not shown in this table.

Note: Parentheses indicate negative values.

1.2 National Inventory Arrangements

The U.S. Environmental Protection Agency (EPA), in cooperation with other U.S. government agencies, prepares the *Inventory of U.S. Greenhouse Gas Emissions and Sinks*. A wide range of agencies and individuals are involved in supplying data to, planning methodological approaches and improvements, reviewing, or preparing portions of the Inventory—including federal and state government authorities, research and academic institutions, industry associations, and private consultants.

Within EPA, the Office of Atmospheric Protection (OAP) is the lead office responsible for the emission and removal calculations provided in the Inventory, as well as the completion of the National Inventory Report and the Common Reporting Format (CRF) tables. EPA's Office of Transportation and Air Quality (OTAQ) and Office of Research and Development (ORD) are also involved in calculating emissions and removals for the Inventory. The U.S. Department of State (DOS) serves as the overall national focal point to the UNFCCC, and EPA's OAP serves as the National Inventory Focal Point for this report, including responding to technical questions and comments on the U.S. Inventory. EPA staff coordinate the annual methodological choice, activity data collection, emission and removal calculations, uncertainty assessment, QA/QC processes, and improvement planning at the individual source and sink category level. EPA's inventory coordinator manages overall compilation of the entire Inventory into the proper reporting format for submission to the UNFCCC, and is responsible for the synthesis of information and for the consistent application of cross-cutting IPCC good practice across the Inventory.

Several other government agencies contribute to the collection and analysis of the underlying activity data used in the Inventory calculations via formal (e.g., interagency agreements) and informal relationships, in addition to the calculation of estimates integrated in the report (e.g., U.S. Department of Agriculture's U.S. Forest Service and Agricultural Service, National Oceanic and Atmospheric Administration, Federal Aviation Administration, and Department of Defense). Other U.S. agencies provide official data for use in the Inventory. The U.S. Department of Energy's Energy Information Administration provides national fuel consumption data and the U.S. Department of Defense provides data on military fuel consumption and use of bunker fuels. Other U.S. agencies providing activity data for use in EPA's emission calculations include: the U.S. Department of Agriculture, National Oceanic and Atmospheric Administration, the U.S. Geological Survey, the Federal Highway Administration, the Department of Transportation, the Bureau of Transportation Statistics, the Department of Commerce, and the Federal Aviation Administration. Academic and research centers also provide activity data and calculations to EPA, as well as individual companies participating in voluntary outreach efforts with EPA. Finally, EPA as the National Inventory Focal Point, in coordination with the U.S. Department of State, officially submits the Inventory to the UNFCCC each April.

1.3 Inventory Process

This section describes EPA's approach to preparing the annual U.S. Inventory, which consists of the National Inventory Report (NIR) and Common Reporting Format (CRF) tables. The inventory coordinator at EPA, with support from the cross-cutting compilation staff, is responsible for coordination of aggregation of all emission and removal estimates, conducting the overall uncertainty analysis of Inventory emissions and trends over time, and ensuring consistency and quality throughout the NIR and CRF tables. Emission and removal calculations, including associated uncertainty analysis for individual sources and/or sink categories are the responsibility of individual source and sink category leads, who are most familiar with each category, underlying data, and the unique national circumstances relevant to its emissions or removals profile. Using IPCC good practice guidance, the individual leads determine the most appropriate methodology and collect the relevant activity data to use in the emission and removal calculations, based upon their expertise in the source or sink category, as well as coordinating with researchers and expert consultants familiar with the sources and sinks. Each year, the coordinator oversees a multi-stage process for collecting information from each individual source and sink category lead to compile all information and data for the Inventory.

Methodology Development, Data Collection, and Emissions and Sink Estimation

Source and sink category leads at EPA collect input data and, as necessary, evaluate or develop the estimation methodology for the individual source and/or sink categories. Because EPA has been preparing the Inventory for many years, for most source and sink categories, the methodology for the previous year is applied to the new "current" year of the Inventory, and inventory analysts collect any new data or update data that have changed from the previous year. If estimates for a new source or sink category are being developed for the first time, or if the methodology is changing for an existing category (e.g., the United States is implementing improvement efforts to apply a higher tiered approach for that category), then the source and/or sink category lead will develop and implement the new or refined methodology, gather the most appropriate activity data and emission factors (or in some cases direct emission measurements) for the entire time series, and conduct any further category-specific review with involvement of relevant experts from industry, government, and universities (see Chapter 9 and Box ES-3 on EPA's approach to recalculations).

Once the methodology is in place and the data are collected, the individual source and sink category leads calculate emission and removal estimates. The individual leads then update or create the relevant report text and accompanying annexes for the Inventory. Source and sink category leads are also responsible for completing the relevant sectoral background tables of the CRF, conducting quality control (QC) checks, preparing relevant category materials for QA, or expert reviews, category-level uncertainty assessments, and reviewing data for publication in EPA's GHG Data Explorer.

The treatment of confidential business information (CBI) in the Inventory is based on EPA internal guidelines, as well as regulations[29] applicable to the data used. EPA has specific procedures in place to safeguard CBI during the inventory compilation process. When information derived from CBI data is used for development of inventory calculations, EPA procedures ensure that these confidential data are sufficiently aggregated to protect confidentiality while still providing useful information for analysis. For example, within the Energy and Industrial Processes and Product Use (IPPU) sectors, EPA has used aggregated facility-level data from the Greenhouse Gas Reporting Program (GHGRP) to develop, inform, and/or quality-assure U.S. emission estimates. In 2014, EPA's GHGRP, with industry engagement, compiled criteria that would be used for aggregating its confidential data to shield the underlying CBI from public disclosure.[30] In the Inventory, EPA is publishing only data values that meet the GHGRP aggregation criteria.[31] Specific uses of aggregated facility-level data are described in the respective methodological sections within those chapters. In addition, EPA uses historical data reported voluntarily to EPA via various voluntary initiatives with U.S. industry (e.g., EPA Voluntary Aluminum Industrial Partnership (VAIP)) and follows guidelines established under the voluntary programs for managing CBI.

Data Compilation and Archiving

The inventory coordinator at EPA with support from the data/document manager collects the source and sink categories' descriptive text and annexes, and also aggregates the emission and removal estimates into a summary data file that links the individual source and sink category data files together. This summary data file contains all of the essential data in one central location, in formats commonly used in the Inventory document. In addition to the data from each source and sink category, other national trend and related data are also gathered in the summary sheet for use in the Executive Summary, Introduction, and Trends sections of the Inventory report (e.g., GDP, population, energy use). Similarly, the recalculation analysis and key category analysis are completed in a separate data file based on output from the summary data file. The uncertainty estimates for each source and sink category are also aggregated into uncertainty summary data files that are used to conduct the overall Inventory uncertainty analysis (see Section 1.7). A Microsoft SharePoint work site, kept on a central server at EPA under the jurisdiction of the inventory coordinator, provides a platform for facilitating collaboration during each compilation phase, but also the efficient storage and archiving of electronic files each annual cycle. Previous final published inventories are also maintained on a report archive page on EPA's Greenhouse Gas Emissions website.[32]

National Inventory Report (NIR) Preparation

The NIR is compiled from the sections developed by each individual source or sink category lead. In addition, the inventory coordinator prepares a brief overview of each chapter that summarizes the emissions and removals from all sources and sinks discussed in the chapters. Also at this time, the Executive Summary, Introduction, Trends in Greenhouse Gas Emissions and Removals, and Recalculations and Improvements chapters are drafted, to reflect the trends and impact from improvements for the time series of the current Inventory. The analysis of trends necessitates gathering supplemental data, including weather and temperature conditions, economic activity and gross domestic product, population, atmospheric conditions, and the annual consumption of electricity, energy, and fossil fuels. Changes in these data are used to explain the trends observed in greenhouse gas emissions in the United States. Furthermore, specific factors that affect individual sectors are researched and discussed. Many of

[31] U.S. EPA Greenhouse Gas Reporting Program. Developments on Publication of Aggregated Greenhouse Gas Data, November 25, 2014. See http://www.epa.gov/ghgreporting/confidential-business-information-ghg-reporting.

[32] See https://www.epa.gov/ghgemissions/us-greenhouse-gas-inventory-report-archive.

the factors that affect emissions are included in the Inventory document as separate analyses or side discussions in boxes within the text. Finally, the uncertainty analysis and key category analysis are compiled and updated in the report as part of final analysis steps. Throughout the report text boxes are also created to provide additional documentation (e.g., definitions) and/or examine the data aggregated in different ways than in the remainder of the document, such as a focus on transportation activities or emissions from electricity generation. The document is prepared to align with the specification of the UNFCCC reporting guidelines for National Inventory Reports while also reflecting national circumstances.

Common Reporting Format Table (CRF) Compilation

The CRF tables are compiled from individual time series input data sheets completed by each individual source or sink category lead, which contain emissions and/or removals and activity data, estimates, methodological and completeness notations and associated explanations. The inventory coordinator and cross-cutting compilation staff import the category data into the UNFCCC's "CRF Reporter" for the United States, assuring consistency and completeness across all sectoral tables. The summary reports for emissions and removals, methods, and emission factors used, the summary tables indicating completeness of estimates (i.e., notation key NE/IE tables), the recalculation tables, and the emission and removal trends tables automatically compiled by the CRF Reporter and reviewed by the inventory coordinator with support from the cross-cutting compilation staff. Internal automated quality checks within the CRF Reporter, as well as reviews by the cross-cutting and category leads, are completed for the entire time series of CRF tables before submission.

QA/QC and Uncertainty

Quality assurance and quality control (QA/QC) and uncertainty analyses are guided by the QA/QC and Inventory coordinators, who help maintain the QA/QC plan and the overall uncertainty analysis procedures (see sections on QA/QC and Uncertainty, below) in collaboration with the broader inventory compilation team. The QA/QC coordinator works closely with the Inventory coordinator and source and sink category leads to ensure that a consistent QA/QC plan is implemented across all inventory categories. Similarly, the Inventory coordinator ensures the uncertainty analysis is implemented consistently across all categories. The inventory QA/QC plan, outlined in Section 1.7 and Annex 8, is consistent with the quality assurance procedures outlined by EPA and IPCC good practices. The QA/QC and uncertainty findings also inform overall improvement planning, and specific improvements are noted in the Planned Improvements sections of respective categories. QA processes are outlined below.

Expert, Public, and UNFCCC Reviews

The compilation of the inventory includes a two-stage review or QA process, in addition to international technical expert review following submission of the report to the UNFCCC. During the first stage (the 30-day Expert Review period), a first draft of sectoral chapters of the document are sent to a select list of technical experts outside of EPA who are not directly involved in preparing estimates. The purpose of the Expert Review is to provide an objective review, encourage feedback on the methodological and data sources used in the current Inventory, especially for sources and sinks which have experienced any changes since the previous Inventory.

Once comments are received and addressed, the second stage, or second draft of the document is released for public review by publishing a notice in the U.S. Federal Register and posting the entire draft Inventory document on the EPA website. The Public Review period allows for a 30-day comment period and is open to the entire U.S. public. Comments received may require further discussion with experts and/or additional research, and specific Inventory improvements requiring further analysis as a result of comments are noted in the relevant category's Planned Improvement section. EPA publishes responses to comments received during both reviews with the publication of the final report on its report website.

Following completion and submission of the report to the UNFCCC, the report also undergoes review by an international team of independent experts for adherence to UNFCCC reporting guidelines and IPCC methodological

guidance.[33] Feedback from all review processes that contribute to improving inventory quality over time are described within each planned improvement section and further in Annex 8. See also the Improvement Planning process discussed below.

Final Submittal to UNFCCC, Document and Data Publication

After the final revisions to incorporate any comments from the Expert Review and Public Review periods, EPA prepares the final NIR and the accompanying CRF tables for electronic reporting. EPA, as the National Inventory focal point, sends the official submission of the U.S. Inventory to the UNFCCC using the CRF Reporter software, coordinating with the U.S. Department of State, the overall UNFCCC focal point. Concurrently, for timely public access, the report is also published on EPA's website.[34] On EPA's website, users can also visualize and download the current time-series estimates from the GHG Inventory Data Explorer Tool,[35] and also download more detailed data presented in tables within the report and report annex in CSV format.

Improvement Planning

Each year, many emission and sink estimates in the *Inventory of U.S. Greenhouse Gas Emissions and Sinks* are recalculated and revised, through the use of better methods and/or data with the goal of improving inventory quality and reducing uncertainties, including the transparency, completeness, consistency, and overall usefulness of the report. In this effort, the United States follows the *2006 IPCC Guidelines* (IPCC 2006), which state, "Both methodological changes and refinements over time are an essential part of improving inventory quality. It is *good practice* to change or refine methods when available data have changed; the previously used method is not consistent with the IPCC guidelines for that category; a category has become key; the previously used method is insufficient to reflect mitigation activities in a transparent manner; the capacity for inventory preparation has increased; improved inventory methods become available; and/or for correction of errors." The EPA's OAP coordinates improvement planning across all sectors and also cross-cutting analyses based on annual review and input from the technical teams leading compilation of each sector's estimates, including continuous improvements to the overall data and document compilation processes. Planned improvements are identified through QA/QC processes (including completeness checks), the key category analysis, and the uncertainty analysis. The inventory coordinator, with input from EPA source and sink category leads, maintains a log of all planned improvements, by sector and cross-cutting, tracking the category significance, specific category improvement, prioritization, anticipated time frame for implementation of each proposed improvement, and status of progress in implementing improvement. Improvements for significant or key categories are usually prioritized across all improvements unless effort would require disproportionate levels of effort and resources relative to improvements for other key categories to address.

1.4 Methodology and Data Sources

Emissions and removals of greenhouse gases from various source and sink categories have been estimated using methodologies that are consistent with the *2006 IPCC Guidelines for National Greenhouse Gas Inventories* (IPCC 2006) and its supplements and refinements. To a great extent, this report makes use of published official economic and physical statistics for activity data, emission factors and other key parameters. Depending on the category, activity data can include fuel consumption or deliveries, vehicle-miles traveled, raw material processed, etc.

[34] See https://www.epa.gov/ghgemissions/inventory-us-greenhouse-gas-emissions-and-sinks.

[35] See https://cfpub.epa.gov/ghgdata/inventoryexplorer/.

Emission factors are factors that relate quantities of emissions to an activity. For more information on data sources see Section 1.2 above, Box 1-1 on use of GHGRP data, and categories' methodology sections for more information on other data sources. In addition to official statistics, the report utilizes findings from academic studies, trade association surveys and statistical reports, along with expert judgment, consistent with the *2006 IPCC Guidelines*.

The methodologies provided in the *2006 IPCC Guidelines* represent foundational methodologies for a variety of source and sink categories, and many of these methodologies continue to be improved and refined as new research and data become available. This report uses those IPCC methodologies when applicable, and supplements them with refined guidance, other available country-specific methodologies and data where possible (e.g., EPA's GHGRP). For example, as noted earlier in this chapter, this report does apply recent supplements and refinements to *2006 IPCC Guidelines* in estimating emissions and removals from coal mining, wastewater treatment and discharge, low voltage anode effects (LVAE) during aluminum production, drained organic soils, and management of wetlands, including flooded lands. Choices made regarding the methodologies and data sources used are provided in the Methodology and Time Series Consistency discussion of each category within each sectoral chapter of the report. Where additional detail is helpful and necessary to explain methodologies and data sources used to estimate emissions, complete documentation is provided in the annexes as indicated in the methodology sections of those respective source categories (e.g., Annex 3.13 for Forest Land Remaining Forest Land and Land Converted to Forest Land).

1.5 Key Categories

The *2006 IPCC Guidelines* (IPCC 2006) and *2019 Refinement to the 2006 IPCC Guidelines* (IPCC 2019) define key categories as "inventory categories which individually, or as a group of categories (for which a common method, emission factor and activity data are applied) are prioritized within the national inventory system because their estimates have a significant influence on a country's total inventory of greenhouse gases in terms of the absolute level, the trend, or the level of uncertainty in emissions or removals. Whenever the term *key category* is used, it includes both source and sink categories."[36] A key category analysis identifies source or sink categories for focusing efforts to improve overall Inventory quality, including additional review when feasible.

The *2006 IPCC Guidelines* (IPCC 2006) and its *2019 Refinement* (2019) define several approaches, both quantitative and qualitative, to conduct a key category analysis and identify key categories both in terms of absolute level and trend, along with consideration of uncertainty. This report employs all approaches to identify key categories for the United States. The first approach, Approach 1, identifies significant or key categories without considering uncertainty in its calculations. An Approach 1 level assessment identifies all source and sink categories that cumulatively account for 95 percent of total level, i.e., total emissions (gross) in a given year when assessed in descending order of absolute magnitude. The level analysis was performed twice, including and excluding sources and sinks from the Land Use, Land-Use Change, and Forestry (LULUCF) sector categories. Similarly, an Approach 1 trend analysis can identify categories with trends that significantly influence overall trends by identifying all source and sink categories that cumulatively account for 95 percent of the sum all the trend assessments (e.g., percent change relative to national trend) when sorted in descending order of absolute magnitude.

The next method, Approach 2, was then implemented to identify any additional key categories not already identified from the Approach 1 level and trend assessments by considering uncertainty. The Approach 2 analysis differs from Approach 1 by incorporating each category's uncertainty assessments in its calculations and was also performed twice, including and excluding LULUCF categories. An Approach 2 level assessment identifies all sources and sink categories that cumulatively account for 90 percent of the sum of all level assessments when sorted in descending order of magnitude. Similarly, an Approach 2 trend analysis can identify categories whose trends

[36] See Chapter 4 Volume 1, "Methodological Choice and Identification of Key Categories" in IPCC (2006) and IPCC (2019). See http://www.ipcc-nggip.iges.or.jp/public/2006gl/index.html.

contribute significantly to overall trends weighting the relative trend difference with the category's relative uncertainty assessment for 2021.

For 2021, based on the key category analysis, excluding the LULUCF sector and uncertainty, 32 categories accounted for 95 percent of emissions. Four categories account for 57 percent of emissions: CO_2 from coal-fired electricity generation, CO_2 from gas fired electricity generation, CO_2 from road transport-related fuel combustion, and CO_2 from substitutes for ozone depleting substances. When considering uncertainties, additional categories such as CH_4 emissions from industrial landfills were also identified as a key category. In the trend analysis, 33 categories were identified as key categories, and when considering uncertainties, 6 additional categories were identified as key. The trend analysis shows that HFC and PFC emissions from substitutes of ozone depleting substances, in addition to CO_2 from coal-fired electricity generation and CO_2 from gas fired electricity generation, and CO_2 from road transport related combustion are also significant with respect to trends over the time series.

When considering the contribution of the LULUCF sector to 2021 emissions and sinks, 43 categories accounted for 95 percent of emissions and sinks, with the most significant category from LULUCF being net CO_2 emission from Forest Land Remaining Forest Land. When considering uncertainties and the contribution of the LULUCF sector, additional categories such as N_2O emissions from forest fires were also identified as a key category. In the trend analysis, 39 categories were identified as key, and when considering uncertainties, 8 additional categories were identified as key. The trend analysis includes additional categories such as non-CO_2 emissions from forest fires as key categories in the LULUCF sector.

Finally, in addition to conducting Approach 1 and 2 level and trend assessments as described above, a qualitative assessment of the source and sinks categories was conducted to capture any additional key categories that were not identified using the previously described quantitative approaches. For this Inventory, no additional categories were identified using qualitative criteria recommend by IPCC, but EPA continues to review its qualitative assessment on an annual basis. Find more information on the key category analysis, including the approach to disaggregation of inventory estimates, see Annex 1 to this report.

Table 1-4: Summary of Key Categories for the United States (1990 and 2021) by Sector

CRF Code and Source/Sink Categories	Gas	Approach 1				Approach 2 (includes uncertainty)				2021 Emissions (MMT CO_2 Eq.)

Note: Parentheses indicate negative values (or sequestration).

1.6 Quality Assurance and Quality Control (QA/QC)

As part of efforts to achieve its stated goals for inventory quality, transparency, and credibility, the United States has developed a quality assurance and quality control plan designed to check, document, and improve the quality of its inventory over time. QA/QC activities on the Inventory are undertaken within the framework of the U.S.

Quality Assurance/Quality Control and Uncertainty Management Plan (QA/QC plan) *for the U.S. Greenhouse Gas Inventory: Procedures Manual for QA/QC and Uncertainty Analysis*.

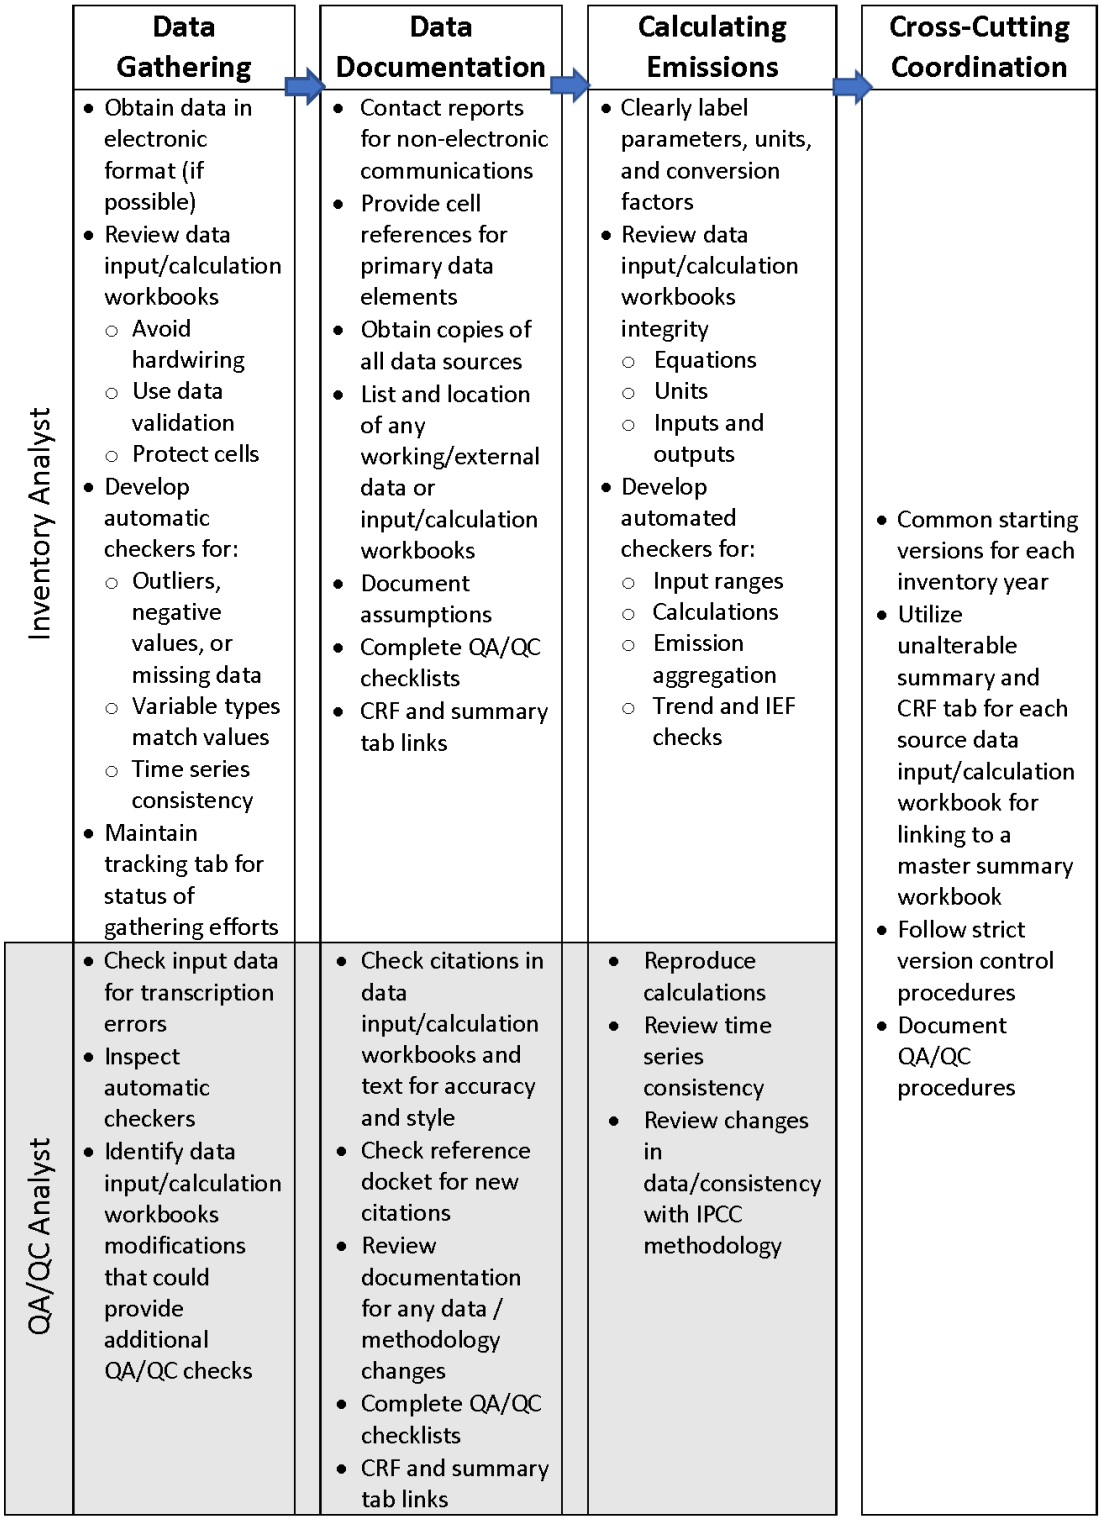
Key attributes of the QA/QC plan are summarized in Figure 1-2. These attributes include:

- *Procedures and Forms:* detailed and specific systems that serve to standardize the process of documenting and archiving information, as well as to guide the implementation of QA/QC and the analysis of uncertainty

- *Implementation of Procedures:* application of QA/QC procedures throughout the whole Inventory development process from initial data collection, through preparation of the emission and removal estimates, to publication of the Inventory

- *Quality Assurance (QA):* expert and public reviews for both the inventory estimates and the Inventory report (which is the primary vehicle for disseminating the results of the inventory development process). The expert technical review conducted by the UNFCCC supplements these QA processes, consistent with the QA good practice and the *2006 IPCC Guidelines* (IPCC 2006)

- *Quality Control (QC)*: application of *General (Tier 1) and Category-specific (Tier 2)* quality controls and checks, as recommended by *2006 IPCC Guidelines* (IPCC 2006), along with consideration of secondary data and category-specific checks (additional Tier 2 QC) in parallel and coordination with the uncertainty assessment; the development of protocols and templates, which provides for more structured communication and integration with the suppliers of secondary information



- *General (Tier 1) and Category-specific (Tier 2) Checks:* quality controls and checks, as recommended by *IPCC Good Practice Guidance* and *2006 IPCC Guidelines* (IPCC 2006)

- *Record Keeping:* provisions to track which procedures have been followed, the results of the QA/QC, uncertainty analysis, and feedback mechanisms for corrective action based on the results of the investigations which provide for continual data quality improvement and guided research efforts.

- *Multi-Year Implementation*: a schedule for coordinating the application of QA/QC procedures across multiple years, especially for category-specific QC, prioritizing key categories

- *Interaction and Coordination:* promoting communication within the EPA, across Federal agencies and departments, state government programs, and research institutions and consulting firms involved in supplying data or preparing estimates for the Inventory. The QA/QC Management Plan itself is intended to be revised and reflect new information that becomes available as the program develops, methods are improved, or additional supporting documents become necessary.

Figure 1-2: U.S. QA/QC Plan Summary

Box 1-3: Examples of Verification Activities

Consistent with IPCC guidance for national greenhouse gas inventories, verification activities include comparisons with emission or removal estimates prepared by other bodies and comparisons with estimates derived from fully independent assessments, e.g., atmospheric concentration measurements. Verification activities provide information to improve inventories and are part of the overall QA/QC system.

Use of lower tier methods. The UNFCCC reporting guidelines require countries to complete a "top-down" reference approach for estimating CO_2 emissions from fossil fuel combustion in addition to their "bottom-up" sectoral methodology for purposes of verification. This estimation method uses alternative methodologies and different data sources than those contained in that section of the Energy chapter. The reference approach estimates fossil fuel consumption by adjusting national aggregate fuel production data for imports, exports, and stock changes rather than relying on end-user consumption surveys (see Annex 4 of this report). The reference approach assumes that once carbon-based fuels are brought into a national economy, they are either saved in some way (e.g., stored in products, kept in fuel stocks, or left unoxidized in ash) or combusted, and therefore the carbon in them is oxidized and released into the atmosphere. Accounting for actual consumption of fuels at the sectoral or sub-national level is not required.

Use of Ambient Measurements Systems for Validation of Emission Inventories. In following the UNFCCC requirement under Article 4.1 to develop and submit national greenhouse gas emission inventories, the emissions and sinks presented in this report are organized by source and sink categories and calculated using internationally accepted methods provided by the IPCC.[37] Several recent studies have estimated emissions at the national or regional level with estimated results that sometimes differ from EPA's estimate of emissions. EPA has engaged with researchers on how remote sensing, ambient measurement, and inverse modeling techniques for estimating greenhouse gas emissions could assist in improving the understanding of inventory estimates. In working with the research community to improve national greenhouse gas inventories, EPA follows guidance from the IPCC on the use of measurements and modeling to validate emission inventories.[38] An area of particular interest in EPA's outreach efforts is how ambient measurement data can be used to assess estimates or potentially be incorporated into the Inventory in a manner consistent with this Inventory report's transparency of its calculation methodologies, and the ability of inverse modeling to attribute emissions and removals from remote sensing to anthropogenic sources, as defined by the IPCC for this report, versus natural sources and sinks.

The *2019 Refinement to the IPCC 2006 Guidelines for National Greenhouse Gas Inventories* (IPCC 2019) Volume 1 General Guidance and Reporting, Chapter 6: Quality Assurance, Quality Control and Verification notes that atmospheric concentration measurements can provide independent data sets as a basis for comparison with inventory estimates. The *2019 Refinement* provides guidance on conducting such comparisons (as summarized in Table 6.2 of IPCC [2019] Volume 1, Chapter 6) and provides guidance on using such comparisons to identify areas of improvement in national inventories (as summarized in Box 6.5 of IPCC [2019] Volume 1, Chapter 6) given the technical complexity of such comparisons. Further, it identified fluorinated gases as particularly suitable for such comparisons. The *2019 Refinement* makes this conclusion for fluorinated gases based on their lack of significant natural sources, their generally long atmospheric lifetimes, their well-known loss mechanisms, and the potential uncertainties in bottom-up inventory methods for some of their sources. Unlike emissions of CO_2, CH_4, and N_2O, emissions of fluorinated greenhouse gases are almost exclusively anthropogenic, meaning that the fluorinated greenhouse gas emission sources included in this Inventory account for the majority of the total U.S. emissions of these gases detectable in the atmosphere.

In this Inventory, EPA presents the results of two comparisons between fluorinated gas emissions inferred from atmospheric measurements and fluorinated gas emissions estimated based on bottom-up measurements and modeling consistent with guidance from the *2019 Refinement*. These comparisons, performed for HFCs and SF_6

[38] See http://www.ipcc-nggip.iges.or.jp/meeting/pdfiles/1003_Uncertainty%20meeting_report.pdf.

respectively, are described under the QA/QC and Verification discussions in Chapter 4, Sections 4.24 Substitution of Ozone Depleting Substances and 4.25 Electrical Transmission and Distribution in the IPPU chapter of this report.

Consistent with the *2019 Refinement*, a key element to facilitate such comparisons is a gridded prior inventory as an input to inverse modeling. To improve the ability to compare the national-level greenhouse gas inventory with measurement results that may be at other scales, a team at Harvard University along with EPA and other coauthors developed a gridded inventory of U.S. anthropogenic methane emissions with 0.1° x 0.1° spatial resolution, monthly temporal resolution, and detailed scale-dependent error characterization. The gridded inventory is designed to be consistent with the 1990 to 2014 U.S. EPA *Inventory of U.S. Greenhouse Gas Emissions and Sinks* estimates for the year 2012, which presents national totals for different source types.[39] This gridded inventory is consistent with the recommendations contained in two National Academies of Science reports examining greenhouse gas emissions data (National Research Council 2010; National Academies of Sciences, Engineering, and Medicine 2018).

Finally, in addition to use of atmospheric concentration measurement data for comparison with Inventory data, information from top-down studies is directly incorporated in the Natural Gas Systems calculations to quantify emissions from certain well blowout events.

In addition, based on the national QA/QC plan for the Inventory, some sector, subsector and category-specific QA/QC and verification checks have been developed. These checks follow the procedures outlined in the national QA/QC plan, tailoring the procedures to the specific documentation and data files associated with individual sources. For each greenhouse gas emissions source or sink category included in this Inventory, a minimum of general or Tier 1 QC analysis has been undertaken. Where QC activities for a particular category go beyond the minimum Tier 1 level, and include category-specific checks (Tier 2) or include verification, further explanation is provided within the respective source or sink category text. Similarly, responses or updates based on comments from the expert, public and the international technical expert reviews (e.g., UNFCCC) are also addressed within the respective source or sink category sections in each sectoral chapter and Annex 8.

The quality control activities described in the U.S. QA/QC plan occur throughout the inventory process; QA/QC is not separate from, but is an integral part of, preparing the Inventory. Quality control—in the form of both good practices (such as documentation procedures) and checks on whether good practices and procedures are being followed—is applied at every stage of inventory development and document preparation. In addition, quality assurance occurs during the Expert Review and the Public Review, in addition to the UNFCCC expert technical review. While all phases significantly contribute to improving inventory quality, the public review phase is also essential for promoting the openness of the inventory development process and the transparency of the inventory data and methods.

The QA/QC plan guides the process of ensuring inventory quality by describing data and methodology checks, developing processes governing peer review and public comments, and developing guidance on conducting an analysis of the uncertainty surrounding the emission and removal estimates. The QA/QC procedures also include feedback loops and provide for corrective actions that are designed to improve the inventory estimates over time.

1.7 Uncertainty Analysis of Emission Estimates

Emissions and removals calculated for the U.S. Inventory reflect best estimates for greenhouse gas source and sink categories in the United States and are continuously revised and improved as new information becomes available. Uncertainty assessment is an essential element of a complete and transparent emissions inventory because it helps inform and prioritize Inventory improvements. For the U.S. Inventory, uncertainty analyses are conducted for each source and sink category as well as for the uncertainties associated with the overall emission (current and base year) and trends estimates. These analyses reflect the quantitative uncertainty in the emission (and removal) estimates associated with uncertainties in their input parameters (e.g., activity data and EFs) and serve to evaluate the relative contribution of individual input parameter uncertainties to the overall Inventory, its trends, and each source and sink category.

The overall level and trend uncertainty estimates for total U.S. greenhouse gas emissions was developed using the IPCC Approach 2 uncertainty estimation methodology (assuming a Normal distribution for Approach 1 estimates), which employs a Monte Carlo Stochastic Simulation technique. The IPCC provides good practice guidance on two approaches—Approach 1 and Approach 2—to estimating uncertainty for both individual and combined source categories. Approach 2 quantifies uncertainties based on a distribution of emissions (or removals), built-up from repeated calculations of emission estimation models and the underlying input parameters, randomly selected according to their known distributions. Approach 2 methodology is applied to each individual source and sink category wherever data and resources are permitted and is also used to quantify the uncertainty in the overall Inventory and its Trends. Source and sink chapters in this report provide additional details on the uncertainty analysis conducted for each source and sink category. See Annex 7 of this report for further details on the U.S. process for estimating uncertainty associated with the overall emission (base and current year) and trends estimates. Consistent with IPCC (IPCC 2006), the United States has ongoing efforts to continue to improve the overall Inventory uncertainty estimates presented in this report.

The United States has also implemented many improvements over the last several years to reduce uncertainties across the source and sink categories and improve Inventory estimates. These improvements largely result from new data sources that provide more accurate data and/or increased data coverage, as well as methodological improvements. Following IPCC good practice, additional efforts to reduce Inventory uncertainties can occur through efforts to incorporate excluded emission and sink categories (see Annex 5), improve estimation methods, and collect more detailed, measured, and representative data. Individual category chapters and Annex 7 both describe current ongoing and planned Inventory and uncertainty analysis improvements. Consistent with IPCC (2006), the United States has ongoing efforts to continue to improve the category-specific uncertainty estimates presented in this report, largely prioritized by considering improvements categories identified as significant by the Key Category Analysis.

Estimates of quantitative uncertainty for the total U.S. greenhouse gas emissions in 1990 (base year) and 2021 are shown below in Table 1-5 and Table 1-6, respectively. The overall uncertainty surrounding the Total Net Emissions is estimated to be -5 to +6 percent in 1990 and -4 to +6 percent in 2021. When the LULUCF sector is excluded from the analysis the uncertainty is estimated to be -2 to +5 percent in 1990 and -2 to +6 percent in 2021.

Table 1-5: Estimated Overall Inventory Quantitative Uncertainty for 1990 (MMT CO_2 Eq. and Percent)

Gas	1990 Emission Estimate (MMT CO_2 Eq.)	Uncertainty Range Relative to Greenhouse Gas Estimate[a]				Mean[b]	Standard Deviation[b]
		(MMT CO_2 Eq.)		(%)		(MMT CO_2 Eq.)	
		Lower Bound[c]	Upper Bound[c]	Lower Bound	Upper Bound		
CO_2	5,121.0	5,008.4	5,356.5	-2%	5%	5,084.8	89.7
CH_4[d]	868.7	784.7	941.9	-10%	8%	742.3	40.2
N_2O[d]	406.3	333.2	616.3	-18%	52%	437.4	72.9
PFC, HFC, SF_6, and NF_3[d]	91.4	81.3	101.7	-11%	11%	195.6	5.5
Total Gross Emissions	**6,487.3**	**6,352.9**	**6,833.1**	**-2%**	**5%**	**6,460.2**	**122.8**
LULUCF Emissions[e]	57.9	54.9	61.5	-5%	6%	78.2	1.7
LULUCF Carbon Stock Change Flux[f]	(938.9)	(1,179.6)	(856.4)	26%	-9%	(901.2)	83.0
LULUCF Sector Net Total[g]	**(881.0)**	**(1,122.0)**	**(798.7)**	**27%**	**-9%**	**(823.1)**	**83.0**
Net Emissions (Sources and Sinks)	**5606.4**	**5,338.3**	**5,920.4**	**-5%**	**6%**	**5,637.1**	**148.2**

[a] The lower and upper bounds for emission estimates correspond to a 95 percent confidence interval, with the lower bound corresponding to 2.5th percentile and the upper bound corresponding to 97.5th percentile.

[b] Mean value indicates the arithmetic average of the simulated emission estimates; standard deviation indicates the extent of deviation of the simulated values from the mean.

[c] The lower and upper bound emission estimates for the sub-source categories do not sum to total emissions because the low and high estimates for total emissions were calculated separately through simulations.

[d] The overall uncertainty estimates did not take into account the uncertainty in the GWP values for CH_4, N_2O and high GWP gases used in the Inventory emission calculations for 1990.

[e] LULUCF emissions include the CH_4 and N_2O emissions reported for Peatlands Remaining Peatlands, Forest Fires, Drained Organic Soils, Grassland Fires, and Coastal Wetlands Remaining Coastal Wetlands; CH_4 emissions from Land Converted to Coastal Wetlands, Land Converted to Flooded Land, and Flooded Land Remaining Flooded Land; and N_2O emissions from forest soils and settlement soils.

[f] LULUCF Carbon Stock Change is the net C stock change from the following categories: Forest Land Remaining Forest Land, Land Converted to Forest Land, Cropland Remaining Cropland, Land Converted to Cropland, Grassland Remaining Grassland, Land Converted to Grassland, Wetlands Remaining Wetlands, Land Converted to Wetlands, Settlements Remaining Settlements, and Land Converted to Settlements. Since the resulting flux is negative the signs of the resulting lower and upper bounds are reversed.

[g] The LULUCF Sector Net Total is the net sum of all CH_4 and N_2O emissions to the atmosphere plus net carbon stock changes.

Notes: Total emissions (excluding emissions for which uncertainty was not quantified) are presented without LULUCF. Net emissions are presented with LULUCF. Totals may not sum due to independent rounding. Parentheses indicate net sequestration.

Table 1-6: Estimated Overall Inventory Quantitative Uncertainty for 2021 (MMT CO_2 Eq. and Percent)

Gas	2021 Emission Estimate (MMT CO_2 Eq.)	Uncertainty Range Relative to Greenhouse Gas Estimate[a]				Mean[b]	Standard Deviation[b]
		(MMT CO_2 Eq.)		(%)		(MMT CO_2 Eq.)	
		Lower Bound[c]	Upper Bound[c]	Lower Bound	Upper Bound		
CO_2	5,032.2	4,916.2	5,241.7	-2%	4%	5,080	84
CH_4[d]	727.4	678.2	810.4	-7%	11%	743	34
N_2O[d]	393.3	312.7	604.9	-20%	54%	436	76
PFC, HFC, SF_6, and NF_3[d]	187.3	178.7	212.0	-5%	13%	196	8
Total Gross Emissions	**6,340.2**	**6,236.1**	**6,695.2**	**-2%**	**6%**	**6,454**	**118**
LULUCF Emissions[e]	77.8	73.5	83.6	-6%	7%	78	3

LULUCF Carbon Stock Change Flux[f]	(832.0)	(1,047.1)	(763.3)	26%	-8%	(903)	73
LULUCF Sector Net Total[g]	**(754.2)**	**(968.5)**	**(685.0)**	**28%**	**-9%**	**(825)**	**73**
Net Emissions (Sources and Sinks)	**5,586.0**	**5,365.4**	**5,903.0**	**-4%**	**6%**	**5,630**	**138**

[a] The lower and upper bounds for emission estimates correspond to a 95 percent confidence interval, with the lower bound corresponding to 2.5th percentile and the upper bound corresponding to 97.5th percentile.

[b] Mean value indicates the arithmetic average of the simulated emission estimates; standard deviation indicates the extent of deviation of the simulated values from the mean.

[c] The lower and upper bound emission estimates for the sub-source categories do not sum to total emissions because the low and high estimates for total emissions were calculated separately through simulations.

[d] The overall uncertainty estimates did not take into account the uncertainty in the GWP values for CH_4, N_2O and high GWP gases used in the Inventory emission calculations for 2021.

[e] LULUCF emissions include the CH_4 and N_2O emissions reported for Peatlands Remaining Peatlands, Forest Fires, Drained Organic Soils, Grassland Fires, and Coastal Wetlands Remaining Coastal Wetlands; CH_4 emissions from Land Converted to Coastal Wetlands, Land Converted to Flooded Land, and Flooded Land Remaining Flooded Land; and N_2O emissions from forest soils and settlement soils.

[f] LULUCF Carbon Stock Change is the net C stock change from the following categories: Forest Land Remaining Forest Land, Land Converted to Forest Land, Cropland Remaining Cropland, Land Converted to Cropland, Grassland Remaining Grassland, Land Converted to Grassland, Wetlands Remaining Wetlands, Land Converted to Wetlands, Settlements Remaining Settlements, and Land Converted to Settlements. Since the resulting flux is negative the signs of the resulting lower and upper bounds are reversed.

[g] The LULUCF Sector Net Total is the net sum of all CH_4 and N_2O emissions to the atmosphere plus net carbon stock changes.

Notes: Total emissions (excluding emissions for which uncertainty was not quantified) are presented without LULUCF. Net emissions are presented with LULUCF. Totals may not sum due to independent rounding. Parentheses indicate net sequestration.

In addition to the estimates of uncertainty associated with the current and base year estimates, Table 1-7 presents the estimates of inventory trend uncertainty. The *2006 IPCC Guidelines* defines trend as the difference in emissions between the base year (i.e., 1990) and the current year (i.e., 2021) Inventory estimates. However, for purposes of understanding the concept of trend uncertainty, the trend is defined in this Inventory as the percentage change in the gross emissions (or net emissions) estimated for the current year, relative to the gross emission (or net emissions) estimated for the base year. The uncertainty associated with this trend is referred to as trend uncertainty and is reported as between -7 and 8 percent at the 95 percent confidence level between 1990 and 2021. This indicates a range of approximately -7 percent below and 8 percent above the trend estimate of -0.4 percent. See Annex 7 for trend uncertainty estimates for individual source and sink categories by gas.

Table 1-7: Quantitative Assessment of Trend Uncertainty (MMT CO_2 Eq. and Percent)

Gas/Source	Base Year Emissions[a]	2021 Emissions	Emissions Trend	Trend Range[b]	
	(MMT CO_2 Eq.)		(%)	(%)	
				Lower Bound	Upper Bound
CO_2	5,121.0	5,032.2	-2%	-6%	3%
CH_4	868.7	727.4	-16%	-24%	-2%
N_2O	406.3	393.3	-3%	-39%	52%
HFCs, PFCs, SF_6, and NF_3	91.4	187.3	105%	86%	147%
Total Gross Emissions[c]	**6,487.3**	**6,340.2**	**-2%**	**-7%**	**3%**
LULUCF Emissions[d]	57.9	77.8	34%	19%	51%
LULUCF Carbon Stock Change Flux[e]	(938.9)	(832.0)	-11%	-30%	12%
LULUCF Sector Net Total[f]	**(881.0)**	**(754.2)**	**-14%**	**-33%**	**10%**
Net Emissions (Sources and Sinks)[c]	**5,606.4**	**5,586.0**	**-0.4%**	**-7%**	**8%**

[a] Base Year is 1990 for all sources.

[b] The trend range represents a 95 percent confidence interval for the emission trend, with the lower bound corresponding to 2.5th percentile value and the upper bound corresponding to 97.5th percentile value.

[c] Totals exclude emissions for which uncertainty was not quantified.

[d] LULUCF emissions include the CH_4 and N_2O emissions reported for Peatlands Remaining Peatlands, Forest Fires, Drained Organic Soils, Grassland Fires, and Coastal Wetlands Remaining Coastal Wetlands; CH_4 emissions from Land Converted to

Coastal Wetlands, Land Converted to Flooded Land, and Flooded Land Remaining Flooded Land; and N_2O emissions from forest soils and settlement soils.

[e] LULUCF Carbon Stock Change is the net C stock change from the following categories: Forest Land Remaining Forest Land, Land Converted to Forest Land, Cropland Remaining Cropland, Land Converted to Cropland, Grassland Remaining Grassland, Land Converted to Grassland, Wetlands Remaining Wetlands, Land Converted to Wetlands, Settlements Remaining Settlements, and Land Converted to Settlements.

[f] The LULUCF Sector Net Total is the net sum of all CH_4 and N_2O emissions to the atmosphere plus net carbon stock changes.

Notes: Totals may not sum due to independent rounding. Parentheses indicate net sequestration. Total emissions (excluding emissions for which uncertainty was not quantified) are presented without LULUCF. Net emissions are presented with LULUCF.

1.8 Completeness

This report, along with its accompanying CRF tables, serves as a thorough assessment of the anthropogenic sources and sinks of greenhouse gas emissions for the United States for the time series 1990 through 2021. This report is intended to be comprehensive and includes the vast majority of emissions and removals identified as anthropogenic, consistent with IPCC and UNFCCC guidelines. In general, sources or sink categories not accounted for in this Inventory are excluded because they are not occurring in the United States and its territories, or because data are unavailable to develop an estimate and/or the categories were determined to be insignificant[40] in terms of overall national emissions per UNFCCC reporting guidelines.

The United States is continually working to improve upon the understanding of such sources and sinks currently not included and seeking to find the data required to estimate related emissions and removals, focusing on categories that are anticipated to be significant. As such improvements are implemented, new emission and removal estimates are quantified and included in the Inventory, improving completeness of national estimates. For a list of sources and sink categories not included and more information on significance of these categories, see Annex 5 and the respective category sections in each sectoral chapter of this report.

1.9 Organization of Report

In accordance with the revision of the UNFCCC reporting guidelines agreed to at the nineteenth Conference of the Parties (UNFCCC 2014), this *Inventory of U.S. Greenhouse Gas Emissions and Sinks* is grouped into five sector-specific chapters consistent with the UN Common Reporting Framework, listed below in Table 1-8. In addition, chapters on Trends in Greenhouse Gas Emissions, Other information, and Recalculations and Improvements to be considered as part of the U.S. Inventory submission are included.

Table 1-8: IPCC Sector Descriptions

Chapter (IPCC Sector)	Activities Included
Energy	Emissions of all greenhouse gases resulting from stationary and mobile energy activities including fuel combustion and fugitive fuel emissions, and non-energy use of fossil fuels.
Industrial Processes and Product Use	Emissions resulting from industrial processes and product use of greenhouse gases.

[40] See paragraph 32 of Decision 24/CP.19, the UNFCCC reporting guidelines on annual inventories for Parties included in Annex 1 to the Convention. Paragraph notes that "…An emission should only be considered insignificant if the likely level of emissions is below 0.05 per cent of the national total GHG emissions, and does not exceed 500 kt CO_2 Eq. The total national aggregate of estimated emissions for all gases and categories considered insignificant shall remain below 0.1 percent of the national total GHG emissions."

Agriculture	Emissions from agricultural activities except fuel combustion, which is addressed under Energy.
Land Use, Land-Use Change, and Forestry	Emissions and removals of CO_2, and emissions of CH_4, and N_2O from land use, land-use change and forestry.
Waste	Emissions from waste management activities.

Within each chapter, emissions are identified by the anthropogenic activity that is the source or sink of the greenhouse gas emissions being estimated (e.g., coal mining). Overall, the following organizational structure is consistently applied throughout this report:

Chapter/IPCC Sector: Overview of emissions and trends for each IPCC defined sector.

CRF Source or Sink Category: Description of category pathway and emission/removal trends based on IPCC methodologies, consistent with UNFCCC reporting guidelines.

Methodology and Time-Series Consistency: Description of analytical methods (e.g., from *2006 IPCC Guidelines,* or country-specific methods) employed to produce emission estimates and identification of data references, primarily for activity data and emission factors, and a discussion of time-series consistency.

Uncertainty: A discussion and quantification of the uncertainty in emission estimates.

QA/QC and Verification: A discussion on steps taken to QA/QC and verify the emission estimates, consistent with the U.S. QA/QC plan, and any key QC findings.

Recalculations Discussion: A discussion of any data or methodological changes that necessitate a recalculation of previous years' emission estimates, and the impact of the recalculation on the emission estimates, if applicable.

Planned Improvements: A discussion on any category-specific planned improvements, if applicable.

Special attention is given to CO_2 from fossil fuel combustion relative to other sources because of its share of emissions and its dominant influence on emission trends. For example, each energy consuming end-use sector (i.e., residential, commercial, industrial, and transportation), as well as the electricity generation sector, is described individually. Additional information for certain source categories and other topics is also provided in several Annexes listed in Table 1-9.

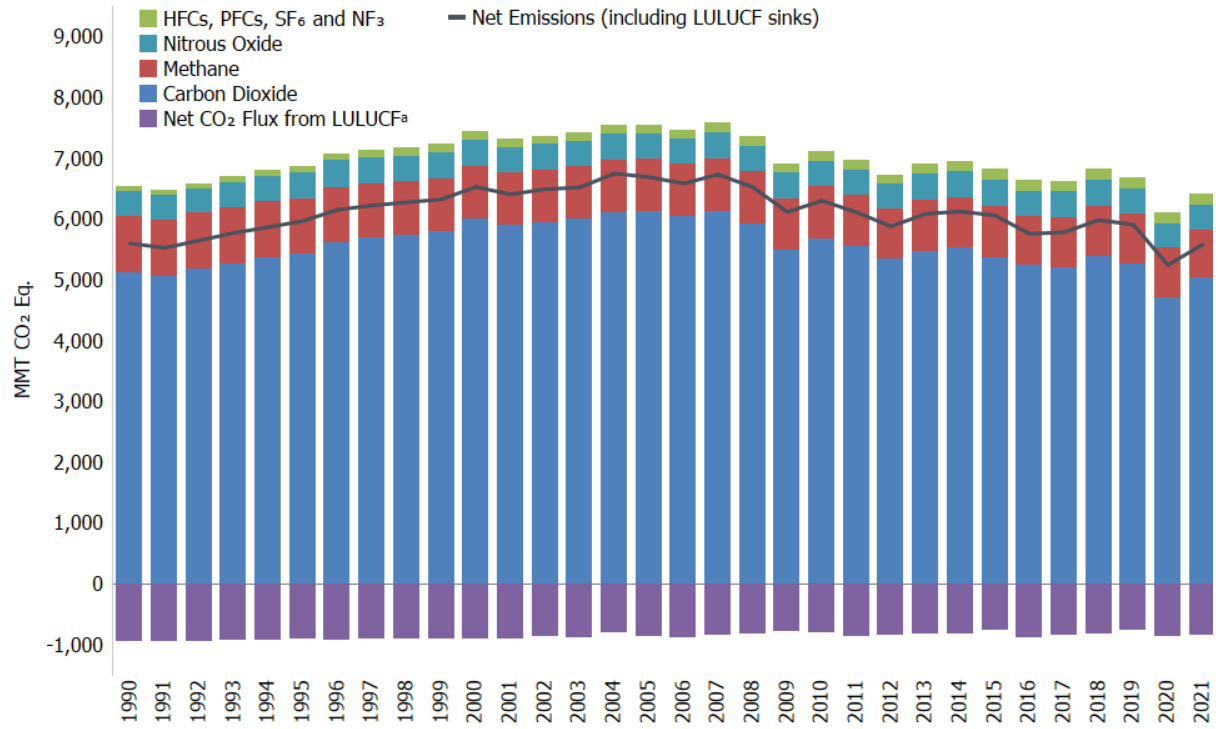
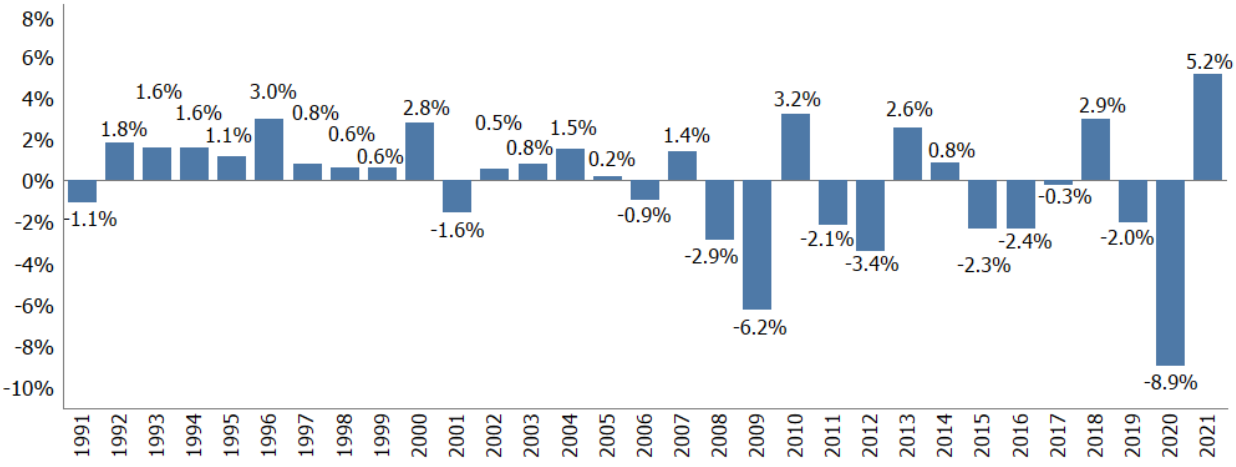
2. Trends in Greenhouse Gas Emissions and Removals



2.1 Overview of U.S. Greenhouse Gas Emissions and Sinks Trends

In 2021, total gross U.S. greenhouse gas emissions were 6,340.2 million metric tons of carbon dioxide equivalent (MMT CO_2 Eq.).[1] Total U.S. emissions have decreased by 2.3 percent from 1990 to 2021, down from a high of 15.8 percent above 1990 levels in 2007. Emissions increased from 2020 to 2021 by 5.2 percent (314.3 MMT CO_2 Eq.). Net emissions (i.e., including sinks) were 5,586.0 MMT CO_2 Eq. in 2021. Overall, net emissions increased 6.4 percent from 2020 to 2021 and decreased 16.6 percent from 2005 levels, as shown in Table 2-1. Between 2020 and 2021, the increase in total greenhouse gas emissions was driven largely by an increase in CO_2 emissions from fossil fuel combustion due to economic activity rebounding after the height of the COVID-19 pandemic. The CO_2 emissions from fossil fuel combustion increased by 6.8 percent from 2020 to 2021, including a 11.4 percent increase in transportation sector emissions and a 7.0 percent increase in electric power sector emissions. The increase in electric power sector emissions was due in part to an increase in electricity demand of 2.4 percent since 2020. Overall there has been a decrease in electric power sector emissions from 1990 through 2021 which reflects the combined impacts of long-term trends in many factors, including population, economic growth, energy markets, technological changes including energy efficiency, and the carbon intensity of energy fuel choices. Between 2019 and 2021, there was still a decrease of 3.5 percent and 4.1 percent in CO_2 emissions from fossil fuel combustion from the transportation and electric power sectors, respectively.

Figure 2-1 and Figure 2-2 illustrate the overall trend in total U.S. emissions and sinks by gas and annual percent changes relative to the previous year since 1990.

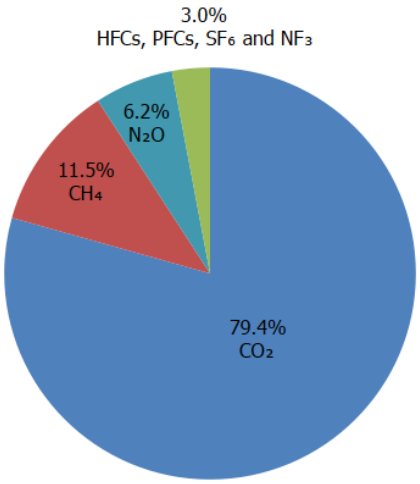


[1] The gross emissions total presented in this report for the United States excludes emissions and sinks from removals from Land Use, Land-Use Change, and Forestry (LULUCF). The net emissions total presented in this report for the United States includes emissions and sinks from removals from LULUCF.

Figure 2-1: U.S. Greenhouse Gas Emissions and Sinks by Gas

[a] The term "flux" is used to describe the exchange of CO_2 to and from the atmosphere, with net flux being either positive or negative depending on the overall balance. Removal and long-term storage of CO_2 from the atmosphere is also referred to as "carbon sequestration."

Figure 2-2: Annual Percent Change in Gross U.S. Greenhouse Gas Emissions Relative to the Previous Year



Emissions and Sinks by Gas

Figure 2-3 illustrates the relative contribution of the greenhouse gases to total gross U.S. emissions in 2021, in CO_2-equivalents (i.e., weighted by global warming potential). The primary greenhouse gas emitted by human activities in the United States is CO_2, representing 79.4 percent of total greenhouse gas emissions. The largest source of CO_2,

and of overall greenhouse gas emissions, is fossil fuel combustion primarily from transportation and power generation. Methane (CH_4) emissions account for 11.5 percent of emissions. The major sources of methane include enteric fermentation associated with domestic livestock, natural gas systems, and decomposition of wastes in landfills. Agricultural soil management, wastewater treatment, stationary sources of fuel combustion, and manure management are the major sources of N_2O emissions. Ozone depleting substance (ODS) substitute emissions were the primary contributor to aggregate hydrofluorocarbon (HFC) emissions. Perfluorocarbon (PFC) emissions were primarily attributable to electronics manufacturing and primary aluminum production. Electrical transmission and distribution systems accounted for most sulfur hexafluoride (SF_6) emissions. The electronics industry is the only source of nitrogen trifluoride (NF_3) emissions.

Figure 2-3: 2021 Gross Total U.S. Greenhouse Gas Emissions by Gas (Percentages based on MMT CO_2 Eq.)

Note: Emissions and removals from Land Use, Land-Use Change, and Forestry are excluded from figure above.

Overall from 1990 to 2021, total emissions of CO_2 decreased by 88.7 MMT CO_2 Eq. (1.7 percent), total emissions of methane (CH_4) decreased by 141.2 MMT CO_2 Eq. (16.3 percent), and total emissions of nitrous oxide (N_2O) decreased by 13.0 MMT CO_2 Eq. (3.2 percent). During the same period, emissions of fluorinated gases including hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), sulfur hexafluoride (SF_6), and nitrogen trifluoride (NF_3) rose by 95.9 MMT CO_2 Eq. (104.8 percent). Despite being emitted in smaller quantities relative to the other principal greenhouse gases, emissions of HFCs, PFCs, SF_6, and NF_3 are significant because many of them have extremely high global warming potentials (GWPs), and, in the cases of PFCs, SF_6, and NF_3, very long atmospheric lifetimes. Conversely, U.S. greenhouse gas emissions were partly offset by carbon (C) sequestration in managed forests, trees in urban areas, agricultural soils, landfilled yard trimmings, and coastal wetlands. These were estimated to offset 13.1 percent (832.0 MMT CO_2 Eq.) of total gross emissions in 2021.

Table 2-1 provides information on trends in emissions and sinks from all U.S. anthropogenic sources and sinks in weighted units of MMT CO_2 Eq., while unweighted gas emissions and sinks in kilotons (kt) are provided in Table 2-2.

Table 2-1: Recent Trends in U.S. Greenhouse Gas Emissions and Sinks (MMT CO_2 Eq.)

Gas/Source	1990	2005	2017	2018	2019	2020	2021
CO_2	**5,121.0**	**6,132.2**	**5,212.2**	**5,377.8**	**5,262.1**	**4,714.6**	**5,032.2**
Fossil Fuel Combustion	4,728.2	5,747.3	4,852.5	4,989.8	4,855.9	4,344.9	4,639.1

+ Does not exceed 0.05 MMT CO_2 Eq.

NO (Not Occurring)

[a] Emissions from biomass and biofuel consumption are not included specifically in Energy sector totals. Net carbon fluxes from changes in biogenic carbon reservoirs are accounted for in the estimates for LULUCF.

[b] Emissions from international bunker fuels are not included in totals.

[c] LULUCF emissions of CH_4 and N_2O are reported separately from gross emissions totals. LULUCF emissions include the CH_4 and N_2O emissions reported for Peatlands Remaining Peatlands, Forest Fires, Drained Organic Soils, Grassland Fires, and Coastal Wetlands Remaining Coastal Wetlands; CH_4 emissions from Land Converted to Coastal Wetlands, Flooded Land Remaining Flooded Land, and Land Converted to Flooded Land; and N_2O emissions from forest soils and settlement soils. Refer to Table 2-8 for a breakout of emissions and removals for LULUCF by gas and source category.

[d] Small amounts of PFC emissions also result from this source.

[e] LULUCF Carbon Stock Change is the net C stock change from the following categories: Forest Land Remaining Forest Land, Land Converted to Forest Land, Cropland Remaining Cropland, Land Converted to Cropland, Grassland Remaining Grassland, Land Converted to Grassland, Wetlands Remaining Wetlands, Land Converted to Wetlands, Settlements Remaining Settlements, and Land Converted to Settlements. Refer to Table 2-8 for a breakout of emissions and removals for LULUCF by gas and source category.

[f] The LULUCF Sector Net Total is the net sum of all LULUCF CH_4 and N_2O emissions to the atmosphere plus LULUCF net carbon stock changes.

Notes: Total (gross) emissions are presented without LULUCF. Net emissions are presented with LULUCF. Totals may not sum due to independent rounding. Parentheses indicate negative values or sequestration.

Table 2-2: Recent Trends in U.S. Greenhouse Gas Emissions and Sinks (kt)

[a] Emissions from biomass and biofuel consumption are not included specifically in Energy sector totals. Net carbon fluxes from changes in biogenic carbon reservoirs are accounted for in the estimates for LULUCF.
[b] Emissions from international bunker fuels are not included in totals.
[c] LULUCF emissions of LULUCF CH_4 and N_2O are reported separately from gross emissions totals. Refer to Table 2-8 for a breakout of emissions and removals for LULUCF by gas and source category.
[d] Small amounts of PFC emissions also result from this source.
Notes: Totals by gas may not sum due to independent rounding. Parentheses indicate negative values or sequestration.

Emissions by IPCC Sector

Emissions and removals of all gases can be summed from each source and sink category into a set of five sectors defined by the UNFCCC Reporting Guidelines and methodological framework provided by the Intergovernmental Panel on Climate Change (IPCC). Figure 2-4 and Table 2-3 illustrate that over the thirty-two-year period of 1990 to 2021, total emissions from the Energy and Waste sectors decreased by 171.4 MMT CO_2 Eq. (3.2 percent) and 66.8 MMT CO_2 Eq. (28.3 percent), respectively. Emissions from Industrial Processes and Product Use and Agriculture grew by 41.0 MMT CO_2 Eq. (12.2 percent) and 50.0 MMT CO_2 Eq. (9.1 percent), respectively. Over the same period, total C sequestration in the Land Use, Land-Use Change, and Forestry (LULUCF) sector decreased by 106.8 MMT CO_2 (11.4 percent decrease in total C sequestration), and emissions from the LULUCF sector increased by 19.9 MMT CO_2 Eq. (34.4 percent).

+ Does not exceed 0.05 MMT CO_2 Eq.

[a] Includes CH_4 and N_2O emissions from fuel combustion.

[b] Emissions from biomass and biofuel consumption are not included specifically in summing Energy sector totals. Net carbon fluxes from changes in biogenic carbon reservoirs are accounted for in the estimates for LULUCF.

[c] Emissions from international bunker fuels are not included in totals.

[d] Total emissions without LULUCF.

[e] LULUCF emissions of CH_4 and N_2O are reported separately from gross emissions totals. LULUCF emissions include the CH_4 and N_2O emissions reported for Peatlands Remaining Peatlands, Forest Fires, Drained Organic Soils, Grassland Fires, and Coastal Wetlands Remaining Coastal Wetlands; CH_4 emissions from Land Converted to Coastal Wetlands, Flooded Land Remaining Flooded Land, and Land Converted to Flooded Land; and N_2O emissions from forest soils and settlement soils. Refer to Table 2-8 for a breakout of emissions and removals for LULUCF by gas and source category.

[f] Net emissions with LULUCF.

Notes: Total (gross) emissions are presented without LULUCF. Net emissions are presented with LULUCF. Totals may not sum due to independent rounding. Parentheses indicate negative values or sequestration.

Energy

Emissions from energy-related activities come from two main categories, including direct emissions associated with fuel use (i.e., fossil fuel combustion, non-energy use of fossil fuels and waste combustion) and fugitive emissions mainly from coal, natural gas, and oil production. Energy emissions also include some categories that are not added to energy sector totals but are instead presented as memo items, including international bunker fuels and biomass emissions. Energy-related activities, primarily fossil fuel combustion, accounted for the vast majority of U.S. CO_2 emissions for the period of 1990 through 2021. Fossil fuel combustion is the largest source of energy-related emissions, with CO_2 being the primary gas emitted (see Figure 2-5). Due to their relative importance, fossil fuel combustion-related CO_2 emissions are considered in detail in the Energy chapter (see Chapter 3).

In 2021, 79.3 percent of the energy used in the United States on a Btu basis was produced through the combustion of fossil fuels. The remaining 20.7 percent came from other energy sources such as hydropower, biomass, nuclear, wind, and solar energy. A discussion of specific trends related to CO_2 and other greenhouse gas emissions from energy use is presented here with more detail in the Energy chapter. Energy-related activities are also responsible for CH_4 and N_2O emissions (41.6 percent and 10.0 percent of total U.S. emissions of each gas, respectively). Table 2-4 presents greenhouse gas emissions from the Energy chapter by source and gas.

+ Does not exceed 0.05 MMT CO_2 Eq.

[a] Emissions from biomass and biofuel consumption are not included specifically in Energy sector totals. Net carbon fluxes from changes in biogenic carbon reservoirs are accounted for in the estimates for LULUCF.

[b] Emissions from international bunker fuels are not included in totals. These values are presented for informational purposes only, in line with the *2006 IPCC Guidelines* and UNFCCC reporting obligations.

Note: Totals may not sum due to independent rounding.

Fossil Fuel Combustion CO_2 Emissions

As the largest contributor to U.S. greenhouse gas emissions, CO_2 from fossil fuel combustion has accounted for approximately 74.8 percent of CO_2-equivalent total gross emissions on average across the time series. Within the United States, fossil fuel combustion accounted for 92.2 percent of CO_2 emissions in 2021. Emissions from this source category include CO_2 associated with the combustion of fossil fuels (coal, natural gas, and petroleum) for energy use. Fossil fuel combustion CO_2 emissions decreased by 1.9 percent (89.1 MMT CO_2 Eq.) from 1990 to 2021 and were responsible for most of the decrease in national emissions during this period. Similarly, CO_2 emissions from fossil fuel combustion have decreased by 1,108.2 MMT CO_2 Eq. since 2005, representing a decrease of 19.3 percent. From 2020 to 2021, these emissions increased by 6.8 percent (294.2 MMT CO_2 Eq.). Historically, changes in emissions from fossil fuel combustion have been the main factor influencing U.S. emission trends.

Changes in CO_2 emissions from fossil fuel combustion since 1990 are affected by many long-term and short-term factors, including population and economic growth, energy price fluctuations and market trends, technological

changes, carbon intensity of energy fuel choices, and seasonal temperatures. Carbon dioxide emissions from coal combustion gradually increased between 1990 and 2007, then began to decrease at a faster rate from 2008 to 2021. Carbon dioxide emissions from natural gas combustion remained relatively constant, with a slight increase between 1990 and 2009, then began to consistently increase between 2010 and 2019. The replacement of coal combustion with natural gas combustion was largely driven by new discoveries of natural gas fields and advancements in drilling technologies, which led to more competitive natural gas prices. On an annual basis, the overall consumption and mix of fossil fuels in the United States fluctuates primarily in response to changes in general economic conditions, overall energy prices, the relative price of different fuels, weather, and the availability of non-fossil alternatives. For example, coal consumption for electric power is influenced by a number of factors, including the relative price of coal and alternative sources, the ability to switch fuels, and longer-term trends in coal markets. Between 2020 and 2021, coal consumption for electric power increased 15.4 percent, a reversal of the overall trend since 2008. However, this followed a 19.2 percent reduction in coal generation between 2019 and 2020 due in part to the COVID-19 pandemic reducing overall demand for fossil fuels across all sectors. There has been a 35.8 percent reduction in overall CO_2 emissions from electric power generation from 2005 to 2021 (see Figure 2-7), reflecting the continued shift in the share of electric power generation from coal to natural gas and renewables since 2005.

Fossil fuel combustion CO_2 emissions also depend on the type of fuel consumed or energy used and its carbon intensity. Producing a unit of heat or electricity using natural gas instead of coal, for example, reduces CO_2 emissions because of the lower C content of natural gas (see Table 3-12 in Chapter 3 for more detail on electricity generation by source and see Table A-19 in Annex 2.1 for more detail on the C content coefficient of different fossil fuels).

Petroleum use is another major driver of CO_2 emissions from fossil fuel combustion, particularly in the transportation sector, which has represented the largest source of CO_2 emissions from fossil fuel combustion since 2017. Emissions from petroleum consumption for transportation increased by 11.5 percent from 2020 to 2021. This trend can be primarily attributed to a 8.1 percent increase in vehicle miles traveled (VMT) from 2020 to 2021 due to the gradual recovery from the COVID-19 pandemic, which limited travel in 2020. From 2019 to 2021, emissions from petroleum consumption for transportation decreased by 4.0 percent following a decrease of 3.7 percent in VMT over that time period. Fuel economy of light-duty vehicles is another important factor. The decline in new light-duty vehicle fuel economy between 1990 and 2004 reflected the increasing market share of light-duty trucks, which grew from about 29.6 percent of new vehicle sales in 1990 to 48.0 percent in 2004. Starting in 2005, average new vehicle fuel economy began to increase while light-duty VMT grew only modestly for much of the period and has slowed the rate of increase of CO_2 emissions.

Overall, across all sectors, there was a 6.8 percent increase in total CO_2 emissions from fossil fuel combustion from 2020 to 2021.

Trends in CO_2 emissions from fossil fuel combustion, separated by end-use sector, are presented in Table 2-5 and Figure 2-6 based on the underlying U.S. energy consumer data collected by the U.S. Energy Information Administration (EIA). Figure 2-7 further describes trends in direct and indirect CO_2 emissions from fossil fuel combustion, separated by end-use sector. Estimates of CO_2 emissions from fossil fuel combustion are calculated from these EIA "end-use sectors" based on total fuel consumption and appropriate fuel properties described below. (Any additional analysis and refinement of the EIA data is further explained in the Energy chapter of this report.)

- *Transportation.* EIA's fuel consumption data for the transportation sector consists of all vehicles whose primary purpose is transporting people and/or goods from one physical location to another.
- *Electric Power.* EIA's fuel consumption data for the electric power sector are comprised of electricity-only and combined-heat-and-power (CHP) plants within the North American Industry Classification System (NAICS) 22 category whose primary business is to sell electricity, or electricity and heat, to the public. (Non-utility power producers are included in this sector as long as they meet the electric power sector definition.)

- *Industry.* EIA statistics for the industrial sector include fossil fuel consumption that occurs in the fields of manufacturing, agriculture, mining, and construction. EIA's fuel consumption data for the industrial sector consist of all facilities and equipment used for producing, processing, or assembling goods. (EIA includes generators that produce electricity and/or useful thermal output primarily to support on-site industrial activities in this sector.)
- *Residential.* EIA's fuel consumption data for the residential sector consist of living quarters for private households.
- *Commercial.* EIA's fuel consumption data for the commercial sector consist of service-providing facilities and equipment from private and public organizations and businesses. (EIA includes generators that produce electricity and/or useful thermal output primarily to support the activities at commercial establishments in this sector.)

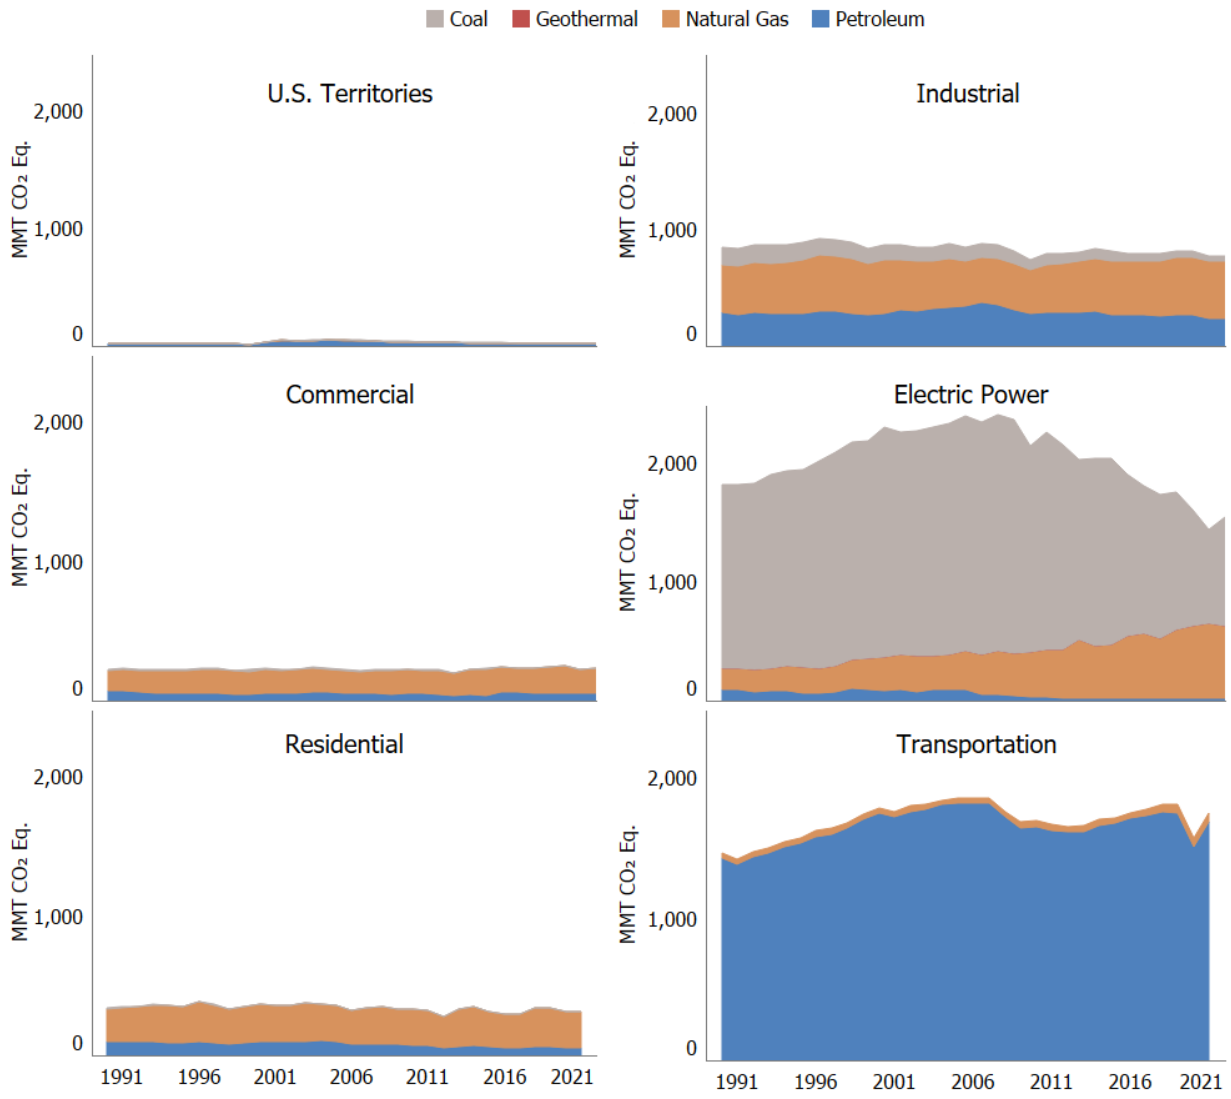

Table 2-5: CO_2 Emissions from Fossil Fuel Combustion by End-Use Sector (MMT CO_2 Eq.)
